Abstract

The thermochemistry of samples of amorphous cellulose, cellulose I, cellulose II, and cellulose III was studied by using oxygen bomb calorimetry, solution calorimetry in which the solvent was cadoxen (a cadmium ethylenediamine solvent), and with a Physical Property Measurement System (PPMS) in zero magnetic field to measure standard massic heat capacities $C_{p,w}^\circ$ over the temperature range $T = (2 \text{ to } 302) \text{ K}$. The samples used in this study were prepared so as to have different values of crystallinity indexes CI and were characterized by X-ray diffraction, by Karl Fischer moisture determination, and by using gel permeation chromatography to determine the weight average degree of polymerization DP_w . NMR measurements on solutions containing the samples dissolved in cadoxen were also performed in an attempt to resolve the issue of the equivalency or non-equivalency of the nuclei in the different forms of cellulose that were dissolved in cadoxen. While large differences in the NMR spectra for the various cellulose samples in cadoxen were not observed, one cannot be absolutely certain that these cellulose samples are chemically equivalent in cadoxen. Equations were derived which allow one to adjust measured property values of cellulose samples having a mass fraction of water w_{H_2O} to a reference value of the mass fraction of water w_{ref} . The measured thermodynamic properties (standard massic enthalpy of combustion $\Delta_c H_w^\circ$, standard massic enthalpy of solution $\Delta_{sol} H_w^\circ$, and $C_{p,w}^\circ$) were used in conjunction with the measured CI values to calculate values of the changes in the standard massic enthalpies of reaction $\Delta_r H_w^{\circ*}$, the standard massic entropies of reaction $\Delta_r S_w^{\circ*}$, the standard massic Gibbs energies of reaction $\Delta_r G_w^{\circ*}$, and the standard massic heat capacity $\Delta C_{p,w}^{\circ*}$ for the interconversion reactions of the pure ($CI = 100$) cellulose allomorphs, *i.e.*, cellulose(am), cellulose I(cr), cellulose II(cr), and cellulose II(cr), at the temperature $T = 298.15 \text{ K}$, the pressure $p^\circ = 0.1 \text{ MPa}$, and $w_{H_2O} = 0.073$. The “*” denotes that the thermodynamic property pertains to pure cellulose allomorphs. Values of standard massic enthalpy differences $\Delta_0^T H_w^\circ$, standard massic entropy differences $\Delta_0^T S_w^\circ$, and the standard massic thermal function $\Phi_w^\circ = \Delta_0^T S_w^\circ - \Delta_0^T H_w^\circ/T$ were calculated from the measured heat capacities for the cellulose samples and for the pure cellulose allomorphs. The extensive literature pertinent to the thermodynamic properties of cellulose has been summarized and, in many cases, property values have been calculated or recalculated from previously reported data. The thermodynamic

property data show that cellulose(am) is the least stable of the cellulose allomorphs considered in this study. However, due to the uncertainties in the measured property values, it is not possible to use these values to order the relative stabilities of the cellulose (I, II, and III) crystalline allomorphs with a reasonable degree of certainty. Nevertheless, based on chemical reactivity information, the qualitative order of stability for these three allomorphs is cellulose III(cr) > cellulose II(cr) > cellulose I β (cr) at $T = 298.15$ K. However, as evidenced by the fact that cellulose I(cr) can be reformed by the application of heat and water to a sample of cellulose III(cr), the differences in the stabilities of these three allomorphs appear to be small and may be temperature dependent. Standard thermodynamic formation properties as well as property values for the conversion reactions of the cellulose allomorphs to α -D-glucose(cr) have been calculated on the assumption that $S_w^\circ \rightarrow 0$ as $T \rightarrow 0$. The values for the standard massic Gibbs energy of reaction $\Delta_r G_w^\circ$ for the conversion of the cellulose allomorphs to α -D-glucose(cr), with the exception of anhydrous cellulose(am), all have positive values and thus are thermodynamically not favored for mass fractions of water $w_{\text{H}_2\text{O}} < 0.073$.

1. Introduction

Cellulose, as the most abundant biological substance on Earth, has been the subject of much study [1]. Four distinct crystalline forms of cellulose are known to exist [2]. Cellulose I exists as an α or a β form [3, 4]. These two forms have essentially the same backbone but differ in their hydrogen bonding patterns and in the conformations of the anhydroglucose residues and the β -1,4 linkages [5]. Cellulose II can be prepared from cellulose I either by treatment with NaOH or by solubilization followed by recrystallization. Cellulose III is obtained by treatment of either cellulose I or cellulose II with liquid ammonia. Samples of cellulose III prepared from cellulose I are often referred to as cellulose III_I in order to distinguish them from the allomorph cellulose III_{II} prepared from cellulose II. The detailed structural differences between cellulose III_I and cellulose III_{II} have not been established. Cellulose IV is obtained by heating cellulose III. In recent years, X-ray and neutron diffraction studies [5-9] have much improved our understanding of the unit cell structure and hydrogen bonding arrangements in the cellulose allomorphs. Additional information on the cellulose allomorphs can be found in the literature [2, 10-12]. Actual samples of cellulose (I, II, and III) share two common features. Specifically, each contains some amorphous cellulose, often at a high mass fraction, and, unless dried thoroughly and handled with extreme care, water is present.

The aim of this study is an improved knowledge of the thermodynamic properties of the following cellulose allomorphs: cellulose(am), cellulose I β (cr), cellulose II(cr), and cellulose III(cr). To accomplish this, we prepared samples of the aforementioned allomorphs having various values of crystallinity indexes. We then measured values of these crystallinity indexes CI , of the weight average degree of polymerization DP_w , and of the mass fraction of water w_{H_2O} in each of these samples. An early decision was made to work with cellulose samples that contained water. The principal reason for this decision was the fact that naturally occurring celluloses, in fact, contain water. Also, when one is working with anhydrous cellulose, the establishment that all water has been removed without changing the character of the cellulose sample [13] is a matter of concern. Additionally, the handling of anhydrous samples of cellulose requires extreme care.

The terminology, symbols, and conventions used in this study are basic to the thermodynamic discussion and treatment of results. The reader is referred to the section “Glossary and conventions” given below.

NMR measurements on solutions containing the samples dissolved in cadoxen, a cadmium ethylenediamine solvent, were also performed. This was followed by measurements of standard massic enthalpies of combustion $\Delta_c H_w^\circ$ of the samples in an oxygen bomb calorimeter, of standard massic heat capacities $C_{p,w}^\circ$ over the temperature range $T = (2 \text{ to } 302) \text{ K}$, and of standard massic enthalpies of solution $\Delta_{\text{sol}} H_w^\circ$ of the cellulose samples in cadoxen. Equations were derived which allow one to adjust measured property values of cellulose samples having a mass fraction of water $w_{\text{H}_2\text{O}}$ to a reference value of the mass fraction of water w_{ref} . Thus, the aforementioned measurements led to values of the standard massic enthalpies of reaction $\Delta_r H_w^{\circ*}$, the standard massic entropies of reaction $\Delta_r S_w^{\circ*}$, and the standard massic Gibbs energies of reaction $\Delta_r G_w^{\circ*}$ for the interconversion reactions of the pure ($CI = 100$) cellulose allomorphs at the temperature $T = 298.15 \text{ K}$, the pressure $p^\circ = 0.1 \text{ MPa}$, and $w_{\text{H}_2\text{O}} = 0.073$. The “*” denotes that the thermodynamic property pertains to pure cellulose allomorphs. Values of standard massic enthalpy differences $\Delta_0^T H_w^\circ$, standard massic entropy differences

$\Delta_0^T S_w^\circ$, and the standard massic thermal function $\Phi_w^\circ = \Delta_0^T S_w^\circ - \Delta_0^T H_w^\circ/T$ were calculated from the measured heat capacities for the cellulose samples and for the pure allomorphs. The extensive literature pertinent to the thermodynamic properties of cellulose has been summarized and, in many cases, property values have been calculated or recalculated from previously reported data. The comparison of results at different values of $w_{\text{H}_2\text{O}}$ required values of the standard massic enthalpies of hydration $\Delta_{\text{hyd}} H_w^{\circ*}$ of the cellulose allomorphs. These values were calculated from results reported in the studies of Nelson [14] and Rees [15]. In addition to having these thermodynamic property values available for practical engineering calculations, a quantitative understanding of the energy relationships amongst the aforementioned allomorphs is important in understanding the biomass recalcitrance problem [16], *i.e.*, the extreme difficulty of converting cellulose to glucose. Standard thermodynamic formation properties as well as property values for the conversion

reactions of the cellulose allomorphs to α -**D**-glucose(cr) have been calculated on the assumption that $S_w^\circ \rightarrow 0$ as $T \rightarrow 0$.

2. Experimental

2.1 Preparation of cellulose samples

A sample of cellulose I β (cotton linters, CAS Number 9004-34-6; catalogue number 22183, lot number BCBB5964V) was obtained from Sigma-Aldrich.¹ Amorphous cellulose samples were prepared from the cellulose I β sample by using a planetary ball mill (Retsh model PM100, Haan, Germany). In order to evaluate the effect of ball milling on the de-crystallization of cellulose, a sample of the cellulose I β was subjected to ball milling for three different time periods, *i.e.* 24 h, 30 h, and 36 h at 25 °C and at 600 rpm using ZrO₂ bowls (volume = 50 mL) and nine ZrO₂ balls. In order to avoid excessive heating of the cellulose sample during ball milling, a 5 min on and 55 min off cycle was employed. Therefore, for 24 h, 30 h, and 36 h periods the effective milling times were 120, 150, and 180 min, respectively. From X-ray diffraction, it was found that each ball milling period (24 h to 36 h) produced essentially amorphous cellulose with no differences in the crystallinity of the three samples. The ball milled samples are designated respectively as amorphous cellulose (24 h), amorphous cellulose (30 h), and amorphous cellulose (36 h).

Cellulose II samples at different degrees of crystallinity were prepared by the aqueous NaOH treatment of cellulose I β (cotton linters - see above) carried out according to the method described by Atalla [17]. To obtain the least crystalline cellulose II sample, a sample of the cotton linters was soaked and stirred in an aqueous NaOH solution (23 mass per cent) at a concentration of 5 g of cotton linters per 100 g of NaOH solution at 25 °C for 50 min under a nitrogen atmosphere. This mix is designated as “mix A”. The NaOH solution was removed from this mix by filtration and then the filter cake was extensively washed with distilled water until the wash had a pH of $\approx$ 7. This sample is designated as cellulose II (25 °C). For obtaining a moderately crystalline cellulose II sample, a portion of mix A was diluted with deionized water to 17.5 mass per cent NaOH and heated at 70 °C for 50 min. This solution was then further heated at 70 °C under a nitrogen cover at successive NaOH concentrations of 15, 12, 10, 8, 4, and 1 mass per cent NaOH.

The lower concentrations of NaOH were obtained by dilution with warm deionized water. A 50 min heating time was used for each NaOH concentration. The mix obtained after the 50 min heating at 1 mass per cent NaOH is designated as “mix B.” After the final washing with the 1 mass per cent NaOH, the cellulose was extensively washed with deionized water at 70 °C to obtain a pH of ≈ 7 . The filtered sample is designated as cellulose II (70 °C). In order to obtain a highly crystalline cellulose II sample, a portion of mix B was dewatered by filtration and immersed in glycerol at 100 °C in a stainless steel reaction vessel (Parr Instrument Co., Model 4520, Moline, IL). After heating the sample at 145 °C for 7 days, the sample was cooled to ≈ 100 °C and washed with boiling deionized water. This sample is designated as cellulose II (145 °C). All samples were freeze dried after washing.

Cellulose III samples were prepared according to the method described earlier [2]. Briefly, a sample of cellulose I β (Fluka cotton linters - see above) having an oven dry equivalent weight (*i.e.*, the mass that would be present if water were to be removed by oven drying) of ≈ 4 g was placed in a stainless steel reaction vessel (Parr Instrument Company, Model 4714, Moline, IL). The reaction vessel was clamped shut, weighed, and then chilled in a (dry ice + acetone) bath at -75 °C to facilitate transfer of liquid ammonia into the reactor at atmospheric pressure. Anhydrous liquid ammonia was added slowly to the reaction vessel in the ratio ≈ 2.5 g ammonia per gram of cellulose by using a stainless steel transfer tube from a liquid ammonia cylinder equipped with an eductor tube. After adding ammonia, the vessel was immediately weighed and then cooled in the (dry ice + acetone) bath at -75 °C for 15 min. The vessel was then immersed in a water bath maintained at ≈ 25 °C until the temperature of the vessel was -33 °C, after which it was removed from the water bath and allowed to vent into a hood until all the ammonia had evaporated. The cellulose sample obtained was observed to be clumped together and retained the shape of the vessel. This clumping may be because the ammonia evaporates very slowly due to the fact that the sample is at ambient pressure. Thus, the sample was gently ground to a powder using a mortar and pestle. The sample obtained is designated as cellulose III (-33 °C). In order to obtain a cellulose III sample of intermediate crystallinity, cotton linters were treated at -75 °C for 15 min as described above, and then the vessel was

immersed in a water bath maintained at 25 °C for 5 min. After completion of this reaction period and prior to its removal from the water bath, the treatment was terminated by immediately depressurizing the vessel in a ventilated hood. The ammonia treated cellulose was removed from the vessel and left in the hood overnight until all ammonia had evaporated. This sample is designated as cellulose III (25 °C). In order to obtain a cellulose III sample of high crystallinity, cotton linters were treated at -75 °C for 15 min as described above and then the vessel was immersed in a water bath maintained at 25 °C for 30 min. The vessel was then placed in a preheated fluidized sand bath (Techne Inc., Burlington, NJ) maintained at 130 °C for 1 h. After concluding this final heat treatment and prior to its removal from the sand bath, the reaction vessel was depressurized by allowing the ammonia to leak out in a ventilated hood. After releasing the ammonia, the vessel was cooled in a water bath maintained at 25 °C. The cellulose sample was removed from the vessel and left in the hood overnight until all the ammonia had evaporated. This sample is designated as cellulose III (130 °C). Unlike the cellulose III (-33 °C) sample, there was no clumping observed in the cellulose III (25 °C) and cellulose III (130 °C) samples. Chemical composition analyses of all the cellulose allomorphs were performed by using a previously described procedure [18]. This analysis showed 99 to 100% glucan content for all the samples suggesting that no degradation of cellulose occurred during the various chemical treatments.

2.2. Preparation and handling of cadoxen

Cadoxen was prepared according to the method of Ladisch [19]. A mass (280 g) of redistilled ethylenediamine (Sigma Aldrich, St. Louis, MO) was mixed with 720 g nanopure water and saturated with CdO (Sigma Aldrich, St. Louis MO). Saturation was carried out in a stirred glass reaction bottle at -5 °C. Approximately 10 g of CdO was added to the bottle every 20 minutes until 90 g had been added. The solution was stirred for 3 h and then left to settle overnight. The clear solution was decanted into a new bottle, and the saturation process was repeated. After settling overnight, the solution was centrifuged in polypropylene centrifuge bottles at $8000 \times G$ for 30 min. The stock solution of cadoxen was stored at 4 °C in glass bottles wrapped in aluminum foil and kept out of the light except for a few minutes during its

transfer to the solution calorimeter. It was observed that a white precipitate formed in the bottom of a bottle holding cadoxen when a sample of cadoxen stock solution was brought from 4 °C to ambient temperature (typically 22.0 °C to 22.5 °C) and allowed to equilibrate at this temperature. While a chemical analysis of the precipitate was not done, it is highly likely that the precipitate is cadmium oxide (CdO). Thus, the cadoxen was preconditioned by allowing for the aforementioned precipitation to take place. Only the clear supernatant from this equilibrated solution was used for the dissolution of the cellulose samples in the solution calorimetry and NMR experiments. The provenance and purities of the materials used in this study is given in table 1.

2.3. X-ray diffraction measurements

Table 1 near here

The crystallinity indexes (*CI*) of cellulose samples were measured by X-ray diffraction (XRD) by using a Rigaku (Tokyo, Japan) Ultima IV diffractometer with CuK α radiation having a wavelength $\lambda(K\alpha 1) = 0.15406$ nm generated at 40 kV and 44 mA. The diffraction intensities of freeze dried samples placed on a quartz substrate were measured in the range of 8° to 42° 2 θ using a step size of 0.02° at a rate of 2° min⁻¹. The crystallinity indexes of the cellulose samples were measured according to the amorphous subtraction method described by Park *et al.* [20, 21]. Briefly, a diffractogram of the 36 h ball-milled cotton linter cellulose prepared according to the method mentioned in section 2.1 was subtracted from the diffractograms of the other cellulose samples so as to remove the influence of the amorphous component in the diffractograms. The ratio of the integrated area of each subtracted diffractogram to the area of the original diffractogram was then calculated and multiplied by 100 to give the *CI* value of the sample. The X-ray diffractograms for the cellulose samples are shown in figure 1.

2.4. Measurement of weight average degree of polymerization

Values of the weight average degree of polymerization (DP_w) of the various forms of cellulose were measured by using gel permeation chromatography (GPC). The procedure was modified from prior methods [22-24]. Cellulose samples were first carbanilated so that they would dissolve in the SEC eluant

tetrahydrofuran (THF). Thus, a 10 mg mass of a vacuum dried cellulose sample was placed in a 5 mL reaction vial and 2 mL of dry pyridine and 0.4 mL of phenyl isocyanate were added. The reaction vial was kept at 70 °C for 24 hours to complete the reaction. Methanol (Baker HPLC grade, 0.4 mL) was added to the reaction mixture to react with the excess phenyl isocyanate at the end of the reaction. The carbanilated cellulose was then precipitated in 26 mL of methanol:water (7:3, v/v) and the precipitate was washed twice with methanol/water (26 mL). The washed cellulose carbanilates were dissolved in THF (Baker HPLC grade, 20 mL) and the solutions filtered (0.45 µm nylon membrane syringe filters) before analysis.

Gel permeation chromatography (GPC) analysis was performed using a high-performance liquid chromatograph (model HP1050, Agilent Technologies Inc.) and five columns (Polymer Laboratories Ltd, 300 mm × 7.5 mm) containing polystyrene-divinyl benzene copolymer gel beads (10 µm diameter) having nominal pore diameters of $(10^3, 10^4, 10^5, 10^6 \text{ and } 10^7) \cdot 10^{-10}$ m, connected in series in order of decreasing pore diameter. A calibration curve based on polystyrene standards of known molar mass (relative molecular mass) was obtained that allowed conversion of retention times into weight average molar mass (M_w). Consequently, all weight average molar mass determined in this work are not absolute but are relative to the calibration curve. The conditions for the chromatography were as follows: flow rate 1.0 mL·min⁻¹; UV detector wavelength 235 nm (with a bandwidth of 10 nm), injection volume 50 µL; and column temperature $t = 25$ °C. Values of the weight average molar mass were calculated using Cirrus GPC software (Polymer Laboratories Ltd). The DP_w values were then calculated by dividing the apparent molar mass by 519 (the molar mass of a repeating unit of carbanilated cellulose with a degree of substitution of 3.0).

2.5. Karl Fischer measurements

The mass fractions of water in the cellulose samples were measured by using Karl Fischer analyses with a Metrohm 795 KFT Titrino automatic titrator and a Metrohm 831 KF coulometer (Metrohm USA, Tampa, FL). The entire apparatus is enclosed in a transparent plastic tent that is kept under a positive pressure with dry nitrogen gas. The temperature was ambient ($\approx 22.0\text{ }^{\circ}\text{C}$) with daily variations generally being less than $\pm 0.3\text{ K}$. Approximately 70 cm^3 of (methanol + formamide) in the volumetric ratio methanol:formamide = 2.5 were placed in the Karl Fischer apparatus and then titrated with Hydranal Composite 2 (Sigma-Aldrich, St. Louis, MO). This titration was continued overnight in order to obtain stable minimal drifts which were typically $< 2 \times 10^{-5}\text{ cm}^3 \cdot \text{s}^{-1}$. The apparatus was calibrated by using $\approx 0.073\text{ g}$ of water-saturated octanol solution which was injected into the Karl Fischer apparatus through a septum. The mass fraction solubility of water in octanol $w = (0.04874 \pm 0.00013)$ at $22.0\text{ }^{\circ}\text{C}$ was taken from the study of Lang [25]. Approximately 0.020 g of each cellulose sample was weighed into a platinum cup. A cup and its contents were then dropped into the Karl Fischer apparatus. The time allowed for the (octanol + water) calibrations was 30 min. A time of 60 min was allowed for the titration of the cellulose samples. The drifts observed during the last 10 min of each titration were consistent with the minimal drifts that were obtained following the overnight titration with no sample in the apparatus. The masses of all samples were determined gravimetrically by using a calibrated balance that had a readability of $\pm 0.01\text{ mg}$.

2.6. NMR measurements

NMR spectra (^1H , ^{13}C , and ^{113}Cd) were obtained for the cellulose samples dissolved in cadoxen. Masses of cellulose were dissolved in cadoxen by lateral shaking (≈ 100 shakes per minute) in a thermostat set at $25.0\text{ }^{\circ}\text{C}$. It was observed that the cellulose samples dissolved completely in the cadoxen within three hours

lateral shaking. The solutions prepared from amorphous (ball-milled) cellulose, cellulose I β , and cellulose III were crystal clear. However, the solutions prepared from cellulose II had a murky appearance. For this reason, the samples of cellulose II were prepared at approximately one-half the mass fraction of the amorphous and cellulose I β and II samples. As a control, one sample of amorphous cellulose (36 h) was run at the same concentration as that used for the cellulose II samples. The collection of the NMR spectra was started within six hours following the preparation of the cellulose samples in cadoxen.

Each NMR sample was prepared by transferring $\approx 0.55 \text{ cm}^3$ of solution by glass pipette into a 5 mm thin-walled precision 600 MHz NMR tube (Wilmad 535-pp-7). A coaxial insert (Wilmad WGS-5BL) was then inserted into the tube containing approximately 0.070 cm^3 of a solution ($28 \text{ mg} \cdot \text{cm}^{-3}$) of trimethylsilylpropionate (TMSP-2,2,3,3-D4, Cambridge Isotope Laboratories DLM-48-1, DSO #12E-319, Lot no. L1-12486) in D₂O (99.9 %, Cambridge Isotope Laboratories DLM-4-25, Lot no. 12E-521) that provided the lock signal and ¹H and ¹³C chemical shift references. The same coaxial insert was used for all samples after appropriate cleaning. All samples were run in a Bruker Avance II 600 MHz NMR spectrometer system operating at a ¹H frequency of 600.13 MHz and equipped with a 5 mm broadband inverse probe. The temperature of the sample, based on a 99.8% methanol-d4 temperature calibration, was 20.0 °C. All pulse sequences used were standard Bruker pulse programs provided in the Topspin software (version 3.1, Bruker). The ¹H spectra were recorded using a 30° pulse angle (zg30 pulse program), 20×10^{-6} spectral width, 64K complex data points (2.73 s acquisition time), 8 s relaxation delay, and either 16 or 64 scans. The ¹H 90° pulse angles were determined for each sample and used in the acquisition of both ¹H and ¹³C spectra. The ¹³C spectra were recorded with ¹H power-gated decoupling (zgpg pulse program), a 240×10^{-6} spectral width, 32k complex data points (0.45 s acquisition time), 1 s relaxation delay, 8192 scans, and 128 dummy scans. The ¹³Cd spectra were recorded using a 90° pulse angle (zg pulse program), 400×10^{-6} spectral width, 128K complex data points (1.22 s acquisition time), 10s relaxation delay and 64 scans. The external chemical shift reference was 0.1 M Cd(ClO₄)₂ in D₂O. Spectra were processed by zero filling to

twice the acquired time domain points, apodized using exponential functions, Fourier transformed, and phase and baseline corrected using Topspin 3.1.

2.7. Combustion calorimetry measurements

The standard massic energies of combustion of several cellulose samples were measured in two different isoperibol static bomb calorimetric systems. The combustion measurements of amorphous cellulose (24 h), cellulose I β , cellulose II (25 °C), cellulose II (70 °C), and cellulose II (145 °C) were carried out with an isoperibol combustion calorimeter previously described in the literature [26, 27] and equipped with a twin valve static bomb made of stainless steel and with an internal volume of 0.342 dm³. This system was calibrated with NIST Thermochemical Standard 39j benzoic acid with a certified standard massic energy of combustion, under bomb conditions, of $-(26434 \pm 3) \text{ J} \cdot \text{g}^{-1}$ [28]. The value of the energy equivalent of the calorimeter was found to be $\alpha(\text{calor}) = (15995.3 \pm 2.0) \text{ J} \cdot \text{K}^{-1}$ (the uncertainty is the standard deviation of the mean) for an average mass of water of 3119.6 g added to the calorimeter. The combustion measurements on the amorphous cellulose (30 h), amorphous cellulose (36 h), cellulose III (-33 °C), cellulose III (25 °C), and cellulose III (130 °C) used another static bomb calorimeter equipped with a twin valve bomb with an internal volume of 0.290 cm³. This calorimeter and the detailed procedure have been described previously [29-31]. The calibration of this bomb calorimeter was performed with the same benzoic acid NIST Thermochemical Standard 39j [28]. From six calibration experiments the value of the energy equivalent of the calorimeter was $\alpha(\text{calor}) = (15551.2 \pm 1.6) \text{ J} \cdot \text{K}^{-1}$ (the uncertainty is one standard deviation of the mean) for an average mass of water added to the calorimeter of 2900.0 g.

For both calorimeters, the calibration experiments were carried out in oxygen at a pressure of 3.04 MPa, with 1.00 cm³ of deionized water added to the bomb, according to the method described by Coops *et al.* [32]. The LABTERMO program [33] was used to acquire data, control the calorimeter temperatures and to compute the adiabatic temperature changes.

The cellulose samples were burned in pellet form at $T = 298.15 \text{ K}$, and with 1.00 cm³ of deionised water introduced into the bomb, which was purged twice to remove air, before being charged with oxygen

to the pressure 3.04 MPa. Details about the calorimetric temperature measurements, electrical energy for ignition, cotton thread fuse and the energetic effect for the amount of nitric acid produced in the combustion have been given previously [31, 34].

The mass of cellulose $m(\text{cell})$ used in each experiment and on which the standard massic energy of combustion was based, was determined from the mass of CO_2 produced, taking into account the mass of CO_2 formed from the combustion of the cotton thread fuse. The procedure given by Hubbard *et al.* [35] was followed to obtain the corrections to the standard state ΔU_Σ and the calculation of the standard massic energy of combustion $\Delta_c U_w^\circ$. The relative atomic masses used throughout this study are those recommended by IUPAC [36].

2.8. Solution calorimetry measurements

The solution calorimeter and the associated measurement procedures have been described previously [37]. Three modifications were made to the apparatus for this investigation. Firstly, while the original gold reaction vessel was used for some initial measurements, it was deemed useful to use a glass reaction vessel so that the contents of the solution calorimeter could be examined visually following the dissolution process. Thus, a glass reaction vessel, holding essentially the same amount of solution (100 cm^3) as the gold reaction vessel, was fabricated. This vessel contained a heater having a resistance of 85.4Ω and the resistance of the heater leads was 0.045Ω . As was done with the gold vessel, the heater leads were thermally well-tempered to the calorimeter vessel. The quartz thermometer probe was the same removable one as used in the gold reaction vessel. The temperature obtained from the quartz thermometer probe was checked periodically against a NIST calibrated platinum resistance thermometer. Secondly, in order to obtain improved stirring and more effective dissolution of the cellulose samples into the cadoxen, a set of stainless steel paddles (width = 1.5 cm; height = 0.80 cm; thickness = 0.065 cm) was fabricated and attached to the stirrer shaft just above the sample holder. There were two paddles. Each paddle was attached to half of a stainless steel cylinder. The two half-cylinders were attached to each other by using two small stainless steel screws going from one half of the cylinder to the other half. The fit of the two halves was tight enough so that the paddle

assembly was firmly held in place to the original removable (sample holder + stirrer) assembly. With the new paddles, a stirring rate of 450 rpm was found to be satisfactory in terms of providing effective stirring without causing deterioration in the quality of the drifts. Thirdly, a small stainless steel connector or coupler (length = 0.60 cm, diameter = 0.64 cm) was fabricated and used to hold firmly the removable (sample holder + stirrer) assembly to the stainless-steel rod that turns that assembly. Small stainless steel screws held the connector to the removable (sample holder + stirrer) assembly and to the stainless-steel rod that turns that assembly. Typically, ≈ 0.020 g of cellulose sample was weighed into a glass sample ampoule which was sealed with a silicone rubber plug, which was then covered with bees wax. Thus, the final mass concentrations of the cellulose allomorphs in the 100.0 cm^3 of cadoxen in the calorimeter were $\approx 0.20\text{ g}\cdot\text{dm}^{-3}$. A small amount of bees wax was also placed along the glass sample ampoule where the ampoule was held in place by the gold sample holder. This served to provide additional assurance that the ampoule would be firmly held in place during an experiment. Additionally, after being affixed to the gold sample holder, the bulbs and their contents were submersed in distilled water in order to see if any leaks were present. Following this, the water was removed by using Kimwipe. Control experiments were also performed by allowing the silicone rubber plugs, the bees wax, the stainless steel, and the gold to sit in cadoxen for ≈ 24 h. There was no visible evidence for reaction of cadoxen with any of these materials. A calibrated 100 cm^3 pipette was used to deliver the cadoxen into the solution calorimeter. Two hours was allowed for a typical solution calorimetry measurement of the heat of solution of a sample of cellulose into cadoxen. The two hour period included a fore period of approximately 15 min. Following the two hour experiment, the calorimeter can was opened and the contents of the glass vessel were viewed. It was found that all of the cellulose samples, with the exception of the cellulose II (25 °C) sample, dissolved well in cadoxen. The cellulose II (25 °C) sample was observed to form a large clump in two separate experiments and, consequently, measurements of the enthalpy of solution of this sample was not possible. After reaction, the (cadoxen + cellulose) was removed from the solution calorimeter. This was followed by washing of the solution calorimeter with HCl(aq) {concentration $c \approx 1.0\text{ M}$ }, with water, and finally with

acetone and air-drying. In the absence of information on the enthalpy of vaporization of cadoxen, the combined correction for (bulb-breaking + vaporization) was taken to be zero.

2.9. Heat-capacity measurements

Heat capacities were measured with logarithmic spacing from $T = (2 \text{ to } 100) \text{ K}$ and in 10 K intervals from $T = (110 \text{ to } 300) \text{ K}$ and at a pressure $p = 1.2 \text{ mPa}$ using a Quantum Design Physical Property Measurement System (PPMS), which uses a thermal relaxation technique. A mass (5 to 13 mg) of each cellulose sample was mixed with about 5 mg of copper strips (Alfa Aesar, 0.99999 mass fraction purity), put into copper cups (mass $\approx 15 \text{ mg}$), and pressed into a disk approximately 3 mm in diameter and 1 mm in height following the method of Shi *et al.* [38]. The disks were successively mounted onto the PPMS puck with Apiezon N grease and then loaded into the PPMS calorimeter where the heat capacities were measured. The possible inaccuracies for the PPMS measurements of the standard massic heat capacities $C_{p,w}^\circ$ following this method are estimated to be $\pm 0.02 \cdot C_{p,w}^\circ$ for $2 < T/\text{K} < 10$ and $\pm 0.01 \cdot C_{p,w}^\circ$ for $10 < T/\text{K} < 302$ [39].

3. Results and discussion

3.1. X-ray diffraction, weight average degrees of polymerization, and Karl Fischer measurements

X-ray diffractograms (XRDs) for the cellulose samples are shown in figure 1. Evidence for the change from cellulose I β to cellulose II is seen in the appearance of a doublet in the XRDs for the 10 $\bar{1}$ and 002 peaks at 2θ values of about 20 and 22 (see figure 1.2). The change from cellulose I β to cellulose III is seen in the position of the 002 peak which shifts from a 2θ value of 23 to 21 as cellulose I β is converted to cellulose III (see figure 1.3). The values of the crystallinity indexes, the weight average degrees of polymerization, and the Karl Fischer measurements are given in tables 2, 3, and 4, respectively. These results are needed for the characterization of the cellulose samples and for subsequent calculations.

Figure 1 and tables 2, 3, and 4 near here

Table 5 and figures 2 to 6 near here

3.2. NMR

NMR provides a convenient tool that can be used to probe the local environment of the nuclei under investigation. As such, it is a natural tool to look to in order to resolve the issue of the equivalency or non-equivalency of the nuclei in the different forms of cellulose that have been dissolved in cadoxen. Since one of the calorimetric approaches being used to measure the enthalpy differences between the crystalline forms of cellulose utilizes cadoxen as a solvent, this matter is of particular interest to this study. The mass fractions and mass concentrations of the cellulose samples used in the NMR measurements are given in table 5. The NMR spectra are shown in figures 2 to 6. In these figures, the spectra were normalized to have approximately the sample peak height for comparison purposes. For the samples having the lower mass fractions of cellulose in cadoxen, the signal to noise ratio was approximately half that of the higher mass fraction samples, as expected. However, for the cellulose II (145 °C) sample, the signal to noise ratio was much less. This is most likely due to incomplete dissolution of the sample which was obscured by its murky appearance. For ^1H – H2 to H6 (see figure 2), it is observed that the chemical shifts and peak shapes are in reasonable agreement except for the first

(top-most) of the cellulose III (-33 °C) samples and for H2 and H3 for the cellulose III (25 °C) and cellulose III (130 °C) samples. Since two replicate measurements made on the cellulose III (-33 °C) sample yielded chemical shifts in agreement with the other cellulose samples, the first measurement involving cellulose III (-33 °C) is judged to be an outlier. It should be noted that, for all of the cellulose II samples and for the last sample of amorphous cellulose (36 h), the mass fraction of cellulose was approximately half of the mass fractions used for the other samples.

For ^{13}C – C1 (see figure 3), the chemical shifts and peak shapes are in good agreement - except that a close examination shows very small downfield shifts {amorphous cellulose (24 h) and cellulose III (-33 °C), $w = 0.009330$ } and up field shifts {cellulose III (-33 °C), $w = 0.009457$ and cellulose III (130 °C)} from the other samples. Based upon the NMR spectra obtained for the cellulose III samples at essentially the same mass fraction of cellulose, these small differences are judged to be within the experimental uncertainties. For ^{13}C – C6 (see figure 4), the chemical shifts and peak shapes are in very good agreement for all samples. For ^{13}C – C2 to C5 (see figure 5), the sample of amorphous cellulose (36 h) with the lowest mass fraction of cellulose in cadoxen shows downfield shifts for C2, C3, and C5. Similar downfield shifts are seen in all of the cellulose II samples. Thus, these downfield shifts may be attributable to the fact that the mass fractions of cellulose in cadoxen are lower than in the other samples. The chemical shifts and peak shapes for the cellulose I β sample are in accord with those seen for the amorphous samples run at the higher concentrations ($w \approx 0.10$). Note that the first (top-most) of the cellulose III (-33 °C) samples shows chemical shifts that deviate significantly from those of the other cellulose samples with the exception of C4, C6 and, perhaps, C5. Also, when compared to each other, differences in chemical shifts for C2 and C3 were seen in the two other samples of cellulose III (-33 °C). The remaining samples of cellulose III also show differences in chemical shifts C2 and C3, with cellulose III (25 °C) also showing a difference in the C5 chemical shift. A single peak was observed in the ^{113}Cd spectrum (see figure 6) which exhibited a trend of up field shifts and significant line broadening with increasing cellulose mass fraction. This trend is attributed to the dynamics of cellulose solvation in cadoxen with the observed resonance representing an

average of chemical shifts for the Cd(II) species in solution. This may be due to a gradual increase in shielding as the coordination environment changes with increasing cellulose concentration. The ^{113}Cd spectra (see figure 6) are particularly interesting in that the samples having the lowest mass fractions have chemical shifts that are distinctly downfield from the samples having the highest mass fractions of cellulose in cadoxen. It should be noted, however, that the chemical shifts show a modest amount of scatter between the various samples and even for replicate preparations - see the cellulose III (-33 °C) spectra in figure 6. In summary, while large differences in the NMR spectra for the various cellulose samples in cadoxen were not observed, one cannot be absolutely certain that these samples are chemically equivalent. This matter is of particular importance in regards to the use of the results of the solution calorimetry measurements. Specifically the calculation of values of standard massic enthalpy differences between the various crystalline forms of cellulose from the measured standard massic enthalpies of solution assumes that the dissolved forms of the various cellulose samples are chemically equivalent (see section 3.4). If this is not the case, the calculated standard massic enthalpy differences would contain a systematic error of unknown magnitude.

3.3. Treatment of enthalpy of combustion data

3.3.1. Stoichiometry of the combustion reaction

The combustion reaction of a sample of cellulose, written on a molar basis, is

Here, u is the average number of $\text{C}_6\text{H}_{10}\text{O}_5$ units in the cellulose and v is the average number of waters of hydration in the sample. Note the inclusion of $(\text{H}_2\text{O})_1$ in the cellulose sample – this represents the unglycosylated ends of the chain which has an H on one end and an OH on the other end. Thus, the relative molecular mass of the anhydrous part of the cellulose sample is

$$M_r(\text{anhyd cell}) = u \cdot M_r(\text{C}_6\text{H}_{10}\text{O}_5) + M_r(\text{H}_2\text{O}). \quad (2)$$

Here, $M_r(\text{C}_6\text{H}_{10}\text{O}_5)$ is the relative molecular mass of $\text{C}_6\text{H}_{10}\text{O}_5$ and $M_r(\text{H}_2\text{O})$ is the relative molecular mass of H_2O . Thus, if u is known, *i.e.*, from a measurement of the degree of polymerization, one can calculate $M_r(\text{anhyd cell})$. The relative molecular mass of the hydrated cellulose sample, is

$$M_r(\text{cell}) = u \cdot M_r(\text{C}_6\text{H}_{10}\text{O}_5) + (v + 1) \cdot M_r(\text{H}_2\text{O}) = M_r(\text{anhyd cell}) + v \cdot M_r(\text{H}_2\text{O}). \quad (3)$$

The mass fractions of the $(\text{H}_2\text{O})_i$, *i.e.* the intrinsic water, and $(\text{H}_2\text{O})_v$ parts of the cellulose sample are given respectively by

$$w_{\text{int}} = M_r(\text{H}_2\text{O})/M_r(\text{cell}), \quad (4)$$

$$w_{\text{hyd}} = v \cdot M_r(\text{H}_2\text{O})/M_r(\text{cell}). \quad (5)$$

The total mass fraction of water in the cellulose sample is

$$w_{\text{H}_2\text{O}} = w_{\text{int}} + w_{\text{hyd}} = \{M_r(\text{H}_2\text{O}) + v \cdot M_r(\text{H}_2\text{O})\}/M_r(\text{cell}) = (v + 1) \cdot M_r(\text{H}_2\text{O})/M_r(\text{cell}) \quad (6)$$

We now consider the combustion reaction of a hypothetical sample of $\text{C}_6\text{H}_{10}\text{O}_5(\text{s})$:

On a standard massic basis, reaction (7) can be written as

$$1 \text{ g } \text{C}_6\text{H}_{10}\text{O}_5(\text{s}) + 6 \cdot \alpha_1 \text{ g } \text{O}_2(\text{g}) = 6 \cdot \alpha_2 \text{ g } \text{CO}_2(\text{g}) + 5 \cdot \alpha_3 \text{ g } \text{H}_2\text{O}(\text{l}), \quad (8)$$

Where $\alpha_1 = M_r(\text{O}_2)/M_r(\text{C}_6\text{H}_{10}\text{O}_5)$, $\alpha_2 = M_r(\text{CO}_2)/M_r(\text{C}_6\text{H}_{10}\text{O}_5)$, and $\alpha_3 = M_r(\text{H}_2\text{O})/M_r(\text{C}_6\text{H}_{10}\text{O}_5)$. The quantities $M_r(\text{O}_2)$ and $M_r(\text{CO}_2)$, are, respectively, the relative molecular masses of O_2 and CO_2 .

One can also represent cellulose as $(\text{C}_6\text{H}_{10}\text{O}_5)_u \cdot w_{\text{H}_2\text{O}}(\text{s})$, for which the combustion reaction (1) can be written on a standard massic basis:

$$1 \text{ g } (\text{C}_6\text{H}_{10}\text{O}_5)_u \cdot w_{\text{H}_2\text{O}}(\text{s}) + 6(1 - w_{\text{H}_2\text{O}}) \cdot \alpha_1 \text{ g } \text{O}_2(\text{g}) = 6(1 - w_{\text{H}_2\text{O}}) \cdot \alpha_2 \text{ g } \text{CO}_2(\text{g}) + 5(1 - w_{\text{H}_2\text{O}}) \cdot \alpha_3 \text{ g } \text{H}_2\text{O}(\text{l}). \quad (9)$$

Note that, written on a massic basis, the amounts of $\text{O}_2(\text{g})$, $\text{CO}_2(\text{g})$, and $\text{H}_2\text{O}(\text{l})$ in the combustion reaction (9) are independent of the number of $\text{C}_6\text{H}_{10}\text{O}_5$ units in the cellulose sample. Thus, for the combustion of a cellulose sample having a mass $m(\text{cell})$, the mass of $\text{CO}_2(\text{g})$ produced is

$$m(\text{CO}_2) = 6\alpha_2(1 - w_{\text{H}_2\text{O}}) \cdot m(\text{cell}). \quad (10)$$

Thus, if $m(\text{CO}_2)$ is known, one can calculate $w_{\text{H}_2\text{O}}$. Then, since $M_r(\text{anhyd cell})$ is known {see eq. (2)}, the combination of eqs. (3) and (6) allows for the calculation of v :

$$v = \{w_{\text{H}_2\text{O}}M_r(\text{anhyd cell}) - M_r(\text{H}_2\text{O})\}/\{M_r(\text{H}_2\text{O}) \cdot (1 - w_{\text{H}_2\text{O}})\}. \quad (11)$$

The relative molecular mass of the (hydrated) cellulose sample $M_r(\text{cell})$ can then be calculated by using eq. (3). In summary, the above treatment allows one to use the mass of $\text{CO}_2(\text{g})$ produced, the measured

value of the degree of polymerization, and, of course, the total mass of the cellulose sample itself to calculate w_{int} , w_{hyd} , $w_{\text{H}_2\text{O}}$, the quantity v , and the relative molecular mass of the cellulose sample.

3.3.2. Adjustment of results to a reference value of the mass fraction of water

We now derive a relationship that will allow one to use the measured value of the standard massic enthalpy of combustion $\Delta_c H_w^\circ\{\text{cell} \cdot w_{\text{H}_2\text{O}}(\text{s})\}$ of a cellulose sample containing a total mass fraction of water $w_{\text{H}_2\text{O}}$ in order to obtain a value of $\Delta_c H_w^\circ\{\text{cell} \cdot w_{\text{ref}}(\text{s})\}$ for that cellulose sample at a reference value of the mass fraction of water w_{ref} . To derive this relationship, we first consider the combustion reaction of a sample of carbon which has some water in it. All of the following reactions are on a standard massic (per gram) basis. The following notation is used: C(s) is solid anhydrous carbon; $w_{\text{H}_2\text{O}}$ is the mass fraction of water in the carbon sample; C $w_{\text{H}_2\text{O}}(\text{s})$ is a sample of solid carbon having a mass fraction of water $w_{\text{H}_2\text{O}}$; and a subscript w denotes that an enthalpy change is on a standard massic basis. The combustion reaction of 1.0 g of C $w_{\text{H}_2\text{O}}(\text{s})$ is:

Here, $\beta_1 = M_r(\text{O}_2)/A_r(\text{C})$, $\beta_2 = M_r(\text{CO}_2)/A_r(\text{C})$, and $A_r(\text{C})$ is the relative atomic mass of C(s). The dehydration reaction of 1.0 g of C $w_{\text{H}_2\text{O}}(\text{s})$ to form $(1 - w_{\text{H}_2\text{O}})$ g of C(s) and $w_{\text{H}_2\text{O}}$ g of H₂O(l) is

Division of reaction (13) by $-(1 - w_{\text{H}_2\text{O}})$ gives the hydration (wetting) reaction of 1.0 g of C(s) to form $\{1/(1 - w_{\text{H}_2\text{O}})\}$ g of C $w_{\text{H}_2\text{O}}(\text{s})$

Reaction (15) is equal to $\{\text{reaction (12)} + (1 - w_{\text{H}_2\text{O}}) \times \text{reaction (14)}\}$:

Division of reaction (15) by $(1 - w_{\text{H}_2\text{O}})$ gives the reaction for the combustion of 1 g of anhydrous C(s):

According to the above reaction scheme, we have the following standard massic enthalpy changes:

$$\Delta_r H_w^\circ(\text{reaction 12}) = \Delta_c H_w^\circ\{\text{C} \cdot w_{\text{H}_2\text{O}}(\text{s})\}, \quad (17)$$

$$\Delta_r H_w^\circ(\text{reaction 14}) = \Delta_{\text{hyd}} H_w^\circ\{C \cdot w_{\text{H}_2\text{O}}(s)\}, \quad (18)$$

$$\begin{aligned} \Delta_r H_w^\circ(\text{reaction 15}) &= \Delta_r H_w^\circ(\text{reaction 12}) + (1 - w_{\text{H}_2\text{O}}) \cdot \Delta_r H_w^\circ(\text{reaction 14}) \\ &= \Delta_c H_w^\circ\{C \cdot w_{\text{H}_2\text{O}}(s)\} + (1 - w_{\text{H}_2\text{O}}) \cdot \Delta_{\text{hyd}} H_w^\circ\{C \cdot w_{\text{H}_2\text{O}}(s)\}, \end{aligned} \quad (19)$$

$$\begin{aligned} \Delta_r H_w^\circ(\text{reaction 16}) &= \{\Delta_r H_w^\circ(\text{reaction 15}) / (1 - w_{\text{H}_2\text{O}})\} \\ &= \{1 / (1 - w_{\text{H}_2\text{O}})\} \cdot \Delta_c H_w^\circ\{C \cdot w_{\text{H}_2\text{O}}(s)\} + \Delta_{\text{hyd}} H_w^\circ\{C \cdot w_{\text{H}_2\text{O}}(s)\}. \end{aligned} \quad (20)$$

But $\Delta_r H_w^\circ(\text{reaction 16})$ is the standard massic enthalpy of combustion of 1 g of anhydrous C(s):

$$\Delta_c H_w^\circ\{C(s)\} = \{1 / (1 - w_{\text{H}_2\text{O}})\} \cdot \Delta_c H_w^\circ\{C \cdot w_{\text{H}_2\text{O}}(s)\} + \Delta_{\text{hyd}} H_w^\circ\{C \cdot w_{\text{H}_2\text{O}}(s)\}. \quad (21)$$

Clearly, one could have derived eq. (21) by using a different mass fraction of water, which we now choose as some reference value w_{ref} instead of $w_{\text{H}_2\text{O}}$, which could be any value. Thus,

$$\Delta_c H_w^\circ\{C(s)\} = \{1 / (1 - w_{\text{ref}})\} \cdot \Delta_c H_w^\circ\{C \cdot w_{\text{ref}}(s)\} + \Delta_{\text{hyd}} H_w^\circ\{C \cdot w_{\text{ref}}(s)\}. \quad (22)$$

Equation (23) is obtained by equating eqs. (21) and (22) and then multiplying by $(1 - w_{\text{ref}})$:

$$\begin{aligned} \Delta_c H_w^\circ\{C \cdot w_{\text{ref}}(s)\} &= \{(1 - w_{\text{ref}}) / (1 - w_{\text{H}_2\text{O}})\} \cdot \Delta_c H_w^\circ\{C \cdot w_{\text{H}_2\text{O}}(s)\} \\ &\quad + (1 - w_{\text{ref}}) \cdot [\Delta_{\text{hyd}} H_w^\circ\{C \cdot w_{\text{H}_2\text{O}}(s)\} - \Delta_{\text{hyd}} H_w^\circ\{C \cdot w_{\text{ref}}(s)\}]. \end{aligned} \quad (23)$$

In eq. (23) the quantities $w_{\text{H}_2\text{O}}$ and $\Delta_c H_w^\circ\{C \cdot w_{\text{H}_2\text{O}}(s)\}$ are measured quantities and w_{ref} has an assigned value.

Thus, they are known quantities. The quantity $\{\Delta_{\text{hyd}} H_w^\circ\{C \cdot w_{\text{H}_2\text{O}}(s)\} - \Delta_{\text{hyd}} H_w^\circ\{C \cdot w_{\text{ref}}(s)\}\}$ is estimated from the enthalpy of wetting data of Rees [15] (see below). Note that $\Delta_{\text{hyd}} H_w^\circ\{C \cdot w_{\text{H}_2\text{O}}(s)\}$ is a standard massic quantity that is based on the mass of anhydrous C(s) and not $C \cdot w_{\text{H}_2\text{O}}(s)$. Finally, it should be noted that when one seeks an accurate value of $\Delta_c H_w^\circ\{C(s)\}$ for an anhydrous substance, eq. (21) is, in fact, the simple and obvious correction that is generally made to $\Delta_c H_w^\circ\{C \cdot w_{\text{H}_2\text{O}}(s)\}$ for the mass fraction of water in a sample.

In many cases, this correction is made with the assumption that the term $\Delta_{\text{hyd}} H_w^\circ\{C \cdot w_{\text{H}_2\text{O}}(s)\}$ is negligible.

As stated above, the notation $\Delta_{\text{hyd}} H_w^\circ\{C \cdot w_{\text{H}_2\text{O}}(s)\}$ denotes the standard massic enthalpy change for the hydration reaction of 1.0 g of C(s) to form $\{1 / (1 - w_{\text{H}_2\text{O}})\}$ g of $C \cdot w_{\text{H}_2\text{O}}(s)$ {see reaction (14)}. This notation is clear and will suffice for now. However, in section 4.0, a more explicit notation is helpful in clarifying the treatment of results from the literature. Specifically, $\Delta_{\text{hyd}} H_w^\circ\{C \cdot w_{\text{H}_2\text{O}}(s)\}$ is written as $\Delta_{\text{hyd}} H_w^\circ\{C, 0 \rightarrow$

$w_{\text{H}_2\text{O}}\}$. The arrow denotes the change from the initial to final mass fraction of water for the hydration reaction of a substance. Information on the cellulose samples is also included in the notation.

Eq. (23) was obtained by considering the combustion of 1.0 g of $\text{C} \cdot w_{\text{H}_2\text{O}}(\text{s})$. However, it can be easily generalized to substances such as $\text{C}_{N1}\text{H}_{N2}\text{O}_{N3} \cdot w_{\text{H}_2\text{O}}(\text{s})$, where $N1$, $N2$, and $N3$ are, respectively, the numbers of carbon, hydrogen, and oxygen atoms in the substance, by following the procedure used above to derive eq. (23). Thus, eq. (23) is valid for the combustion reaction of a substance such as cellulose. Accordingly, we use eq. (23) and values of $\Delta_c H_w^\circ\{\text{cell} \cdot w_{\text{H}_2\text{O}}(\text{s})\}$ obtained with samples that have different values of moisture content $w_{\text{H}_2\text{O}}$ to calculate values of $\Delta_c H_w^\circ\{\text{cell} \cdot w_{\text{ref}}(\text{s})\}$ at w_{ref} , the reference value of the mass fraction moisture content, which we take to be $w_{\text{ref}} = 0.073$, the mean value of w obtained from the cellulose samples obtained by using the Karl Fischer method. Eq. (23) is the useful working equation that provides an adjustment or normalization to a common reference basis for the results of this study and allows for the calculation of the standard massic enthalpies of conversion of one crystalline form of cellulose to another crystalline form at a specified value of w_{ref} .

The data needed for the adjustment to a reference mass fraction of water $w_{\text{ref}} = 0.073$ by using eq. (23) is estimated from the study of Rees [15] who gives a plot (see figure 4 in [15]) of “the heat of wetting (cal/gm of dry material) vs. moisture regain %” for five different cellulose samples. From the slopes of the five curves shown in this plot in the “moisture regain region” 4 to 10 per cent (*i.e.*, $w_{\text{H}_2\text{O}} = 0.04$ to 0.10), we obtain the value $\eta = (3.46 \pm 0.7) \text{ J} \cdot (\text{g dry material})^{-1}$ that corresponds to a change of 0.01 in the value of $w_{\text{H}_2\text{O}}$. Since $\Delta_{\text{hyd}} H_w^\circ$ for cellulose is exothermic, a sample of cellulose having $w_{\text{H}_2\text{O}} < 0.073$ will require a positive adjustment to the measured value of $\Delta_c H_w^\circ$ in order to obtain $\Delta_c H_w^\circ(w_{\text{ref}} = 0.073)$. The adjustment is negative if $w_{\text{H}_2\text{O}} > 0.073$. Additionally, a factor of 100 is needed because the value of η pertains to a change in $w_{\text{H}_2\text{O}}$ of 0.01. Thus, the last term in square brackets in eq. (23) is estimated by use of the following equation:

$$\Delta_{\text{hyd}} H_w^\circ\{\text{C} \cdot w_{\text{H}_2\text{O}}(\text{s})\} - \Delta_{\text{hyd}} H_w^\circ\{\text{C} \cdot w_{\text{ref}}(\text{s})\} = \eta(0.073 - w_{\text{H}_2\text{O}}) \cdot 100. \quad (24)$$

In our treatment of uncertainties, we shall assume that the adjustment of values of $\Delta_{\text{sol}}H_w^\circ$ to $w_{\text{ref}} = 0.073$ is uncertain by 20 per cent. Interestingly, the study of Rees [15], done in 1948, appears to be the most extensive and definitive study of the enthalpy of hydration of cellulose samples in the literature. A later, carefully done study by Morrison and Dzieciuch [40] on the enthalpy of hydration of cotton is in accord with the results of Rees [15].

3.3.3. Calculation of standard massic enthalpy differences between cellulose allomorphs

The treatment described above allows for the calculation of the state of hydration (w_{int} , w_{hyd} , $w_{\text{H}_2\text{O}}$, and the quantity ν), the relative molecular masses, and values of the standard massic enthalpies of combustion $\Delta_c H_w^\circ\{\text{cell} \cdot w_{\text{ref}}(\text{s})\}$ that have been normalized to a reference value of the mass fraction moisture content w_{ref} . Having done the normalization, one has values of $\Delta_c H_w^\circ\{\text{cell} \cdot w_{\text{ref}}(\text{s})\}$ for each of the twelve cellulose samples studied in this investigation at a reference mass fraction of water $w_{\text{ref}} = 0.073$. However, excepting the amorphous cellulose samples, the samples of cellulose I β , cellulose II, and cellulose III are each a mixture of that respective form of cellulose and amorphous cellulose. The mass fraction of crystalline cellulose w_{cr} in each of the samples of cellulose I β , II, and III is obtained by using the measured values of the crystallinity indexes CI (see table 2), *i.e.*, $w_{\text{cr}} = 0.01 \cdot CI$. Thus, the measured standard massic enthalpy of combustion for a cellulose sample (cellulose I is used as the example) is taken to be:

$$\Delta_c H_w^\circ\{\text{cell I} \cdot w_{\text{ref}}(\text{s})\} = w_{\text{cr}} \cdot \Delta_c H_w^{\circ*}\{\text{cell I} \cdot w_{\text{ref}}(\text{cr})\} + (1 - w_{\text{cr}}) \cdot \Delta_c H_w^{\circ*}\{\text{cell} \cdot w_{\text{ref}}(\text{am})\}, \quad (25)$$

where $\Delta_c H_w^{\circ*}\{\text{cell I} \cdot w_{\text{ref}}(\text{cr})\}$ is the standard massic enthalpy of combustion of pure ($CI = 100$) cellulose I(cr) and $\Delta_c H_w^{\circ*}\{\text{cell} \cdot w_{\text{ref}}(\text{am})\}$ is the standard massic enthalpy of combustion of pure amorphous cellulose. All of these enthalpies of combustion pertain to w_{ref} . Since, the quantity $\Delta_c H_w^{\circ*}\{\text{cell} \cdot w_{\text{ref}}(\text{am})\}$ is known from direct measurements on the three amorphous cellulose samples, eq. (25) can be used to calculate values of $\Delta_c H_w^{\circ*}\{\text{cell I} \cdot w_{\text{ref}}(\text{cr})\}$. Clearly, this procedure can also be used for the cellulose II and III samples.

The values of $\Delta_c H_w^{\circ*}\{\text{cell am} \cdot w_{\text{ref}}(\text{s})\}$, $\Delta_c H_w^{\circ*}\{\text{cell I} \cdot w_{\text{ref}}(\text{s})\}$, $\Delta_c H_w^{\circ*}\{\text{cell II} \cdot w_{\text{ref}}(\text{s})\}$, and $\Delta_c H_w^{\circ*}\{\text{cell III} \cdot w_{\text{ref}}(\text{s})\}$ can then be used to calculate values of standard massic enthalpy changes for the following reactions:

$$\text{cellulose} \cdot w_{\text{ref}}(\text{am}) = \text{cellulose I} \cdot w_{\text{ref}}(\text{cr}), \quad (26)$$

$$\text{cellulose } w_{\text{ref}}(\text{am}) = \text{cellulose II } w_{\text{ref}}(\text{cr}), \quad (27)$$

$$\text{cellulose } w_{\text{ref}}(\text{am}) = \text{cellulose III } w_{\text{ref}}(\text{cr}), \quad (28)$$

$$\text{cellulose I } w_{\text{ref}}(\text{cr}) = \text{cellulose II } w_{\text{ref}}(\text{cr}), \quad (29)$$

$$\text{cellulose I } w_{\text{ref}}(\text{cr}) = \text{cellulose III } w_{\text{ref}}(\text{cr}), \quad (30)$$

$$\text{cellulose II } w_{\text{ref}}(\text{cr}) = \text{cellulose III } w_{\text{ref}}(\text{cr}). \quad (31)$$

Thus,

$$\Delta_r H_w^{\circ*}(\text{reaction 26}) = \Delta_c H_w^{\circ*} \{ \text{cell} \cdot w_{\text{ref}}(\text{am}) \} - \Delta_c H_w^{\circ*} \{ \text{cell I} \cdot w_{\text{ref}}(\text{cr}) \}, \quad (32)$$

$$\Delta_r H_w^{\circ*}(\text{reaction 27}) = \Delta_c H_w^{\circ*} \{ \text{cell} \cdot w_{\text{ref}}(\text{am}) \} - \Delta_c H_w^{\circ*} \{ \text{cell II} \cdot w_{\text{ref}}(\text{cr}) \}, \quad (33)$$

$$\Delta_r H_w^{\circ*}(\text{reaction 28}) = \Delta_c H_w^{\circ*} \{ \text{cell} \cdot w_{\text{ref}}(\text{am}) \} - \Delta_c H_w^{\circ*} \{ \text{cell III} \cdot w_{\text{ref}}(\text{cr}) \}, \quad (34)$$

$$\Delta_r H_w^{\circ*}(\text{reaction 29}) = \Delta_c H_w^{\circ*} \{ \text{cell I} \cdot w_{\text{ref}}(\text{cr}) \} - \Delta_c H_w^{\circ*} \{ \text{cell II} \cdot w_{\text{ref}}(\text{cr}) \}, \quad (35)$$

$$\Delta_r H_w^{\circ*}(\text{reaction 30}) = \Delta_c H_w^{\circ*} \{ \text{cell I} \cdot w_{\text{ref}}(\text{cr}) \} - \Delta_c H_w^{\circ*} \{ \text{cell III} \cdot w_{\text{ref}}(\text{cr}) \}, \quad (36)$$

$$\Delta_r H_w^{\circ*}(\text{reaction 31}) = \Delta_c H_w^{\circ*} \{ \text{cell II} \cdot w_{\text{ref}}(\text{cr}) \} - \Delta_c H_w^{\circ*} \{ \text{cell III} \cdot w_{\text{ref}}(\text{cr}) \}. \quad (37)$$

As mentioned above, it is important to recognize that when written on a standard massic basis, the amounts of $\text{O}_2(\text{g})$, $\text{CO}_2(\text{g})$, and $\text{H}_2\text{O}(\text{l})$ in the combustion reaction (9) are independent of the number of $\text{C}_6\text{H}_{10}\text{O}_5$ units in the cellulose sample. Also, note that, since all of the cellulose samples have been brought to a common value of w_{ref} , the terms involving $\text{O}_2(\text{g})$, $\text{CO}_2(\text{g})$, and $\text{H}_2\text{O}(\text{l})$ in reaction (9) will cancel when combining the combustion reactions for two different forms of cellulose. Implicit in this calculation is the assumption that the values of $\Delta_c H_w^{\circ*}$ do not depend on the degree of polymerization, *i.e.*, the quantity u .

3.4. Treatment of enthalpy of solution data

The solution reaction of a sample of cellulose into cadoxen written on a molar basis is

As above (see section 3.3.1), we again have eqs. (2) to (6) and eq. (11), which allows one to calculate

$M_r(\text{anhyd cell})$, $M_r(\text{cell})$, w_{int} , w_{hyd} , and v if u and $w_{\text{H}_2\text{O}}$ are known. The treatment of the enthalpy of solution data is similar to the treatment of the enthalpy of combustion data. Specifically, a relationship is derived

that allows one to use the measured value of the standard massic enthalpy of solution $\Delta_{\text{sol}}H_w^\circ\{\text{cell}\cdot w_{\text{H}_2\text{O}}(\text{s})\}$ of a cellulose sample having a mass fraction of water $w_{\text{H}_2\text{O}}$ in order to obtain a value of $\Delta_{\text{sol}}H_w^\circ\{\text{cell}\cdot w_{\text{ref}}(\text{s})\}$ of that cellulose sample at a reference value of the mass fraction of water w_{ref} . To do this, we consider reactions (39) to (45), which are all on a standard massic basis. Here, “(cad)” denotes that a substance is dissolved in cadoxen. The remaining notation is the same as that used in section 3.3 above. The dissolution reaction of 1.0 g of $\text{cell}\cdot w_{\text{H}_2\text{O}}(\text{s})$ into cadoxen is:

The dehydration reaction of 1.0 g of $\text{cell}\cdot w_{\text{H}_2\text{O}}(\text{s})$ to form $(1 - w_{\text{H}_2\text{O}})$ g of $\text{cell}(\text{s})$ and $w_{\text{H}_2\text{O}}$ g of $\text{H}_2\text{O}(\text{l})$ is:

Division of reaction (40) by $-(1 - w_{\text{H}_2\text{O}})$ gives the hydration reaction of 1.0 g of $\text{cell}(\text{s})$:

Reaction (42) is {reaction (39) - reaction (40)}:

The solution reaction for $w_{\text{H}_2\text{O}}$ g of $\text{H}_2\text{O}(\text{l})$ into cadoxen is:

Reaction (44) is {reaction (42) - reaction (43)}:

Division of reaction (44) by $(1 - w_{\text{H}_2\text{O}})$ gives the solution reaction of 1.0 g of $\text{cell}(\text{s})$ into cadoxen:

We now consider the enthalpy changes for the above reactions that pertain to a sample of cellulose having a mass fraction of water $w_{\text{H}_2\text{O}}$. The quantity $\Delta_r H_w^\circ(\text{reaction 39})$ is the standard massic enthalpy of solution of $\text{cell}\cdot w_{\text{H}_2\text{O}}(\text{s})$ into cadoxen, *i.e.*,

$$\Delta_r H_w^\circ(\text{reaction 39}) = \Delta_{\text{sol}}H_w^\circ\{\text{cell}\cdot w_{\text{H}_2\text{O}}(\text{s})\}. \quad (46)$$

$\Delta_r H_w^\circ(\text{reaction 40})$ is the negative of the standard massic enthalpy of hydration of $(1 - w_{\text{H}_2\text{O}})$ g of anhydrous cellulose, *i.e.*, $\text{cell}(\text{s})$, to form 1.0 g of $\text{cell}\cdot w_{\text{H}_2\text{O}}(\text{s})$. And, $\Delta_r H_w^\circ(\text{reaction 41})$ is the standard massic enthalpy of hydration of 1.0 g of $\text{cell}(\text{s})$ to form $\{1/(1 - w_{\text{H}_2\text{O}})\}$ g of $\text{cell}\cdot w_{\text{H}_2\text{O}}(\text{s})$. Thus,

$$\Delta_r H_w^\circ(\text{reaction 40}) = -(1 - w_{\text{H}_2\text{O}}) \cdot \Delta_{\text{hyd}} H_w^\circ\{\text{cell} \cdot w_{\text{H}_2\text{O}}(\text{s})\}, \quad (47)$$

$$\Delta_r H_w^\circ(\text{reaction 41}) = \Delta_{\text{hyd}} H_w^\circ\{\text{cell} \cdot w_{\text{H}_2\text{O}}(\text{s})\}. \quad (48)$$

The quantity $\Delta_r H_w^\circ(\text{reaction 42})$ is equal to $\{\Delta_r H_w^\circ(\text{reaction 39}) - \Delta_r H_w^\circ(\text{reaction 40})\}$. Then, by using eqs. (46) and (47)

$$\Delta_r H_w^\circ(\text{reaction 42}) = \Delta_{\text{sol}} H_w^\circ\{\text{cell} \cdot w_{\text{H}_2\text{O}}(\text{s})\} + (1 - w_{\text{H}_2\text{O}}) \cdot \Delta_{\text{hyd}} H_w^\circ\{\text{cell} \cdot w_{\text{H}_2\text{O}}(\text{s})\}. \quad (49)$$

$\Delta_r H_w^\circ(\text{reaction 43})$ is the enthalpy of solution of $w_{\text{H}_2\text{O}}$ g of $\text{H}_2\text{O}(\text{l})$ into cadoxen, *i.e.*,

$$\Delta_r H_w^\circ(\text{reaction 43}) = w_{\text{H}_2\text{O}} \cdot \Delta_{\text{sol}} H_w^\circ\{\text{H}_2\text{O}(\text{l})\}. \quad (50)$$

Then,

$$\Delta_r H_w^\circ(\text{reaction 44}) = \Delta_r H_w^\circ(\text{reaction 42}) - \Delta_r H_w^\circ(\text{reaction 43})$$

$$\Delta_r H_w^\circ(\text{reaction 44}) = \Delta_{\text{sol}} H_w^\circ\{\text{cell} \cdot w_{\text{H}_2\text{O}}(\text{s})\} + (1 - w_{\text{H}_2\text{O}}) \cdot \Delta_{\text{hyd}} H_w^\circ\{\text{cell} \cdot w_{\text{H}_2\text{O}}(\text{s})\} - w_{\text{H}_2\text{O}} \cdot \Delta_{\text{sol}} H_w^\circ\{\text{H}_2\text{O}(\text{l})\}. \quad (51)$$

The quantity $\Delta_r H_w^\circ(\text{reaction 45})$ is the standard massic enthalpy of solution of 1.0 g of anhydrous cellulose into cadoxen, *i.e.* $\Delta_{\text{sol}} H_w^\circ\{\text{cell}(\text{s})\}$. Thus,

$$\Delta_r H_w^\circ(\text{reaction 45}) = \Delta_{\text{sol}} H_w^\circ\{\text{cell}(\text{s})\} = \Delta_r H_w^\circ(\text{reaction 44}) / (1 - w_{\text{H}_2\text{O}}), \quad (52)$$

$$\begin{aligned} \Delta_{\text{sol}} H_w^\circ\{\text{cell}(\text{s})\} &= \{1 / (1 - w_{\text{H}_2\text{O}})\} \cdot \Delta_{\text{sol}} H_w^\circ\{\text{cell} \cdot w_{\text{H}_2\text{O}}(\text{s})\} + \Delta_{\text{hyd}} H_w^\circ\{\text{cell} \cdot w_{\text{H}_2\text{O}}(\text{s})\} \\ &\quad - \{w_{\text{H}_2\text{O}} / (1 - w_{\text{H}_2\text{O}})\} \cdot \Delta_{\text{sol}} H_w^\circ\{\text{H}_2\text{O}(\text{l})\}. \end{aligned} \quad (53)$$

Clearly, one could have derived eq. (53) by using a different mass fraction of water, which we now choose as some reference value w_{ref} instead of $w_{\text{H}_2\text{O}}$. Thus,

$$\begin{aligned} \Delta_{\text{sol}} H_w^\circ\{\text{cell}(\text{s})\} &= \{1 / (1 - w_{\text{ref}})\} \cdot \Delta_{\text{sol}} H_w^\circ\{\text{cell} \cdot w_{\text{ref}}(\text{s})\} + \Delta_{\text{hyd}} H_w^\circ\{\text{cell} \cdot w_{\text{ref}}(\text{s})\} \\ &\quad - \{w_{\text{ref}} / (1 - w_{\text{ref}})\} \cdot \Delta_{\text{sol}} H_w^\circ\{\text{H}_2\text{O}(\text{l})\}. \end{aligned} \quad (54)$$

By equating eqs. (53) and (54), one has

$$\begin{aligned} &\{1 / (1 - w_{\text{ref}})\} \cdot \Delta_{\text{sol}} H_w^\circ\{\text{cell} \cdot w_{\text{ref}}(\text{s})\} + \Delta_{\text{hyd}} H_w^\circ\{\text{cell} \cdot w_{\text{ref}}(\text{s})\} - \{w_{\text{ref}} / (1 - w_{\text{ref}})\} \cdot \Delta_{\text{sol}} H_w^\circ\{\text{H}_2\text{O}(\text{l})\} = \\ &\{1 / (1 - w_{\text{H}_2\text{O}})\} \cdot \Delta_{\text{sol}} H_w^\circ\{\text{cell} \cdot w_{\text{H}_2\text{O}}(\text{s})\} + \Delta_{\text{hyd}} H_w^\circ\{\text{cell} \cdot w_{\text{H}_2\text{O}}(\text{s})\} - \{w_{\text{H}_2\text{O}} / (1 - w_{\text{H}_2\text{O}})\} \cdot \Delta_{\text{sol}} H_w^\circ\{\text{H}_2\text{O}(\text{l})\}. \end{aligned} \quad (55)$$

Multiplication of eq. (55) by $(1 - w_{\text{ref}})$ and rearrangement gives the useful working equation

$$\begin{aligned} \Delta_{\text{sol}} H_w^\circ\{\text{cell} \cdot w_{\text{ref}}(\text{s})\} &= \{(1 - w_{\text{ref}}) / (1 - w_{\text{H}_2\text{O}})\} \cdot \Delta_{\text{sol}} H_w^\circ\{\text{cell} \cdot w_{\text{H}_2\text{O}}(\text{s})\} + (1 - w_{\text{ref}}) \cdot [\Delta_{\text{hyd}} H_w^\circ\{\text{cell} \cdot w_{\text{H}_2\text{O}}(\text{s})\} \\ &\quad - \Delta_{\text{hyd}} H_w^\circ\{\text{cell} \cdot w_{\text{ref}}(\text{s})\}] + \{(w_{\text{ref}} - w_{\text{H}_2\text{O}}) / (1 - w_{\text{H}_2\text{O}})\} \cdot \Delta_{\text{sol}} H_w^\circ\{\text{H}_2\text{O}(\text{l})\}. \end{aligned} \quad (56)$$

The quantities $w_{\text{H}_2\text{O}}$, $\Delta_{\text{sol}}H_w^\circ\{\text{cell}\cdot w_{\text{H}_2\text{O}}(\text{s})\}$, and $\Delta_{\text{sol}}H_w^\circ\{\text{H}_2\text{O}(\text{l})\}$ in eq. (56) are measured quantities and w_{ref} has an assigned value. Thus, they are all known quantities. The quantity $[\Delta_{\text{hyd}}H_w^\circ\{\text{cell}\cdot w_{\text{H}_2\text{O}}(\text{s})\} - \Delta_{\text{hyd}}H_w^\circ\{\text{cell}\cdot w_{\text{ref}}(\text{s})\}]$ was discussed in section 3.3.2 and it is estimated from the “heat of wetting” data of Rees [15] {see eq. (24)}. Thus, one can use eqs. (56) and (24) and values of $\Delta_{\text{sol}}H_w^\circ\{\text{cell}\cdot w_{\text{H}_2\text{O}}(\text{s})\}$ obtained with samples that differ in their values of moisture content $w_{\text{H}_2\text{O}}$ over a modest range to calculate values of $\Delta_{\text{sol}}H_w^\circ\{\text{cell}\cdot w_{\text{ref}}(\text{s})\}$ at a reference value of the mass fraction moisture content w_{ref} . This adjustment or normalization, as described for the combustion data, serves to provide a common reference basis for the results of this study and allows, as described in section 3.3.3, for the calculation of the standard massic enthalpies of conversion of one crystalline form of cellulose to another crystalline form. Note that eq. (56) contains an additional term $\{(w_{\text{ref}} - w_{\text{H}_2\text{O}})/(1 - w_{\text{H}_2\text{O}})\} \cdot \Delta_{\text{sol}}H_w^\circ\{\text{H}_2\text{O}(\text{l})\}$ that is not present in eq. (23). It turns out that this last term is negligible in comparison to the two other terms on the right-hand side of eq. (56).

The treatment of the standard massic enthalpy of solution data then parallels the treatment of the standard massic enthalpy of combustion data. Thus, by analogy to eq. (25), one has

$$\Delta_{\text{sol}}H_w^\circ\{\text{cell I}\cdot w_{\text{ref}}(\text{s})\} = w_{\text{cr}} \cdot \Delta_{\text{sol}}H_w^*\{\text{cell I}\cdot w_{\text{ref}}(\text{cr})\} + (1 - w_{\text{cr}}) \cdot \Delta_{\text{sol}}H_w^*\{\text{cell}\cdot w_{\text{ref}}(\text{am})\}. \quad (57)$$

As above (see section 3.3.3), $w_{\text{cr}} = 0.01 \cdot CI$. The only change from eq. (25) is that one is now dealing with standard massic enthalpies of solution rather than standard massic enthalpies of combustion. Also, by analogy to eqs. (32) to (37), one has

$$\Delta_r H_w^{\circ*}(\text{reaction 26}) = \Delta_{\text{sol}}H_w^{\circ*}\{\text{cell}\cdot w_{\text{ref}}(\text{am})\} - \Delta_{\text{sol}}H_w^{\circ*}\{\text{cell I}\cdot w_{\text{ref}}(\text{cr})\}, \quad (58)$$

$$\Delta_r H_w^{\circ*}(\text{reaction 27}) = \Delta_{\text{sol}}H_w^{\circ*}\{\text{cell}\cdot w_{\text{ref}}(\text{am})\} - \Delta_{\text{sol}}H_w^{\circ*}\{\text{cell II}\cdot w_{\text{ref}}(\text{cr})\}, \quad (59)$$

$$\Delta_r H_w^{\circ*}(\text{reaction 28}) = \Delta_{\text{sol}}H_w^{\circ*}\{\text{cell}\cdot w_{\text{ref}}(\text{am})\} - \Delta_{\text{sol}}H_w^{\circ*}\{\text{cell III}\cdot w_{\text{ref}}(\text{cr})\}, \quad (60)$$

$$\Delta_r H_w^{\circ*}(\text{reaction 29}) = \Delta_{\text{sol}}H_w^{\circ*}\{\text{cell I}\cdot w_{\text{ref}}(\text{cr})\} - \Delta_{\text{sol}}H_w^{\circ*}\{\text{cell II}\cdot w_{\text{ref}}(\text{cr})\}, \quad (61)$$

$$\Delta_r H_w^{\circ*}(\text{reaction 30}) = \Delta_{\text{sol}}H_w^{\circ*}\{\text{cell I}\cdot w_{\text{ref}}(\text{cr})\} - \Delta_{\text{sol}}H_w^{\circ*}\{\text{cell III}\cdot w_{\text{ref}}(\text{cr})\}, \quad (62)$$

$$\Delta_r H_w^{\circ*}(\text{reaction 31}) = \Delta_{\text{sol}}H_w^{\circ*}\{\text{cell II}\cdot w_{\text{ref}}(\text{cr})\} - \Delta_{\text{sol}}H_w^{\circ*}\{\text{cell III}\cdot w_{\text{ref}}(\text{cr})\}. \quad (63)$$

Note that in combining the values of the standard massic enthalpies of solution to obtain eqs. (58) to (63), it is assumed that the various forms of cellulose in cadoxen are chemically equivalent. However, if this is not

the case, this assumption could lead to systematic errors that would be extremely difficult, if not impossible, to obtain corrections for. This problem does not exist for the combustion experiments, where it is clear that the products of the combustion reactions $\{\text{CO}_2(\text{g})$ and $\text{H}_2\text{O}(\text{l})\}$, are chemically equivalent.

3.5. Treatment of heat-capacity data

The treatment of the heat capacities and related thermal data is very similar to the treatments used for the standard massic enthalpies of combustion and solution (see sections 3.3 and 3.4). We first consider the treatment of values of the standard massic entropy differences $\Delta_0^T S_w^\circ = (S_{298.15}^\circ - S_0^\circ)_w$ for the cellulose samples. The values of $\Delta_0^T S_w^\circ$ can be adjusted to the reference mass fraction of water $w_{\text{ref}} = 0.073$ by assuming that

$$\Delta_0^T S_w^\circ\{\text{cell} \cdot w_{\text{H}_2\text{O}}(\text{s})\} = (1 - w_{\text{H}_2\text{O}}) \cdot \Delta_0^T S_w^\circ(\text{anhyd cell}) + w_{\text{H}_2\text{O}} \cdot S_{298.15, w}^\circ\{\text{H}_2\text{O}(\text{cr, hex})\}, \quad (64)$$

$$\Delta_0^T S_w^\circ\{\text{cell} \cdot w_{\text{ref}}(\text{s})\} = (1 - w_{\text{ref}}) \cdot \Delta_0^T S_w^\circ(\text{anhyd cell}) + w_{\text{ref}} \cdot S_{298.15, w}^\circ\{\text{H}_2\text{O}(\text{cr, hex})\}. \quad (65)$$

Here, $\Delta_0^T S_w^\circ\{\text{cell} \cdot w_{\text{H}_2\text{O}}(\text{s})\}$ is the measured standard massic entropy difference for a cellulose sample having a mass fraction of water $w_{\text{H}_2\text{O}}$, $\Delta_0^T S_w^\circ\{\text{cell} \cdot w_{\text{ref}}(\text{s})\}$ is the standard massic entropy difference for a cellulose sample having a mass fraction of water w_{ref} , $\Delta_0^T S_w^\circ(\text{anhyd cell})$ is the standard massic entropy difference for anhydrous cellulose, and $S_{T, w}^\circ\{\text{H}_2\text{O}(\text{cr, hex})\}$ is the standard massic entropy of crystalline hexagonal ice. The temperature T is arbitrary, but will be taken to be $T = 298.15$ K. Here, we have used the standard massic entropy of crystalline hexagonal ice to approximate the standard massic entropy of the water that is bound to cellulose [41, 42]. By solving for $\Delta_0^T S_w^\circ(\text{anhyd cell})$ in eqs. (64) and (65) and then equating these two solutions, one obtains

$$\begin{aligned} \Delta_0^T S_w^\circ\{\text{cell} \cdot w_{\text{ref}}(\text{s})\} = & \left[\frac{(1 - w_{\text{ref}})}{(1 - w_{\text{H}_2\text{O}})} \right] \cdot \left[\Delta_0^T S_w^\circ\{\text{cell} \cdot w_{\text{H}_2\text{O}}(\text{s})\} - w_{\text{H}_2\text{O}} \cdot S_{T, w}^\circ\{\text{H}_2\text{O}(\text{cr, hex})\} \right] \\ & + w_{\text{ref}} \cdot S_{T, w}^\circ\{\text{H}_2\text{O}(\text{cr, hex})\}. \end{aligned} \quad (66)$$

This equation allows for the adjustment of the measured values of $\Delta_0^T S_w^\circ\{\text{cell} \cdot w_{\text{H}_2\text{O}}(\text{s})\}$ to a reference value of the moisture content w_{ref} . Equations for related thermal functions have the same form as eq. (66):

$$\begin{aligned} X\{\text{cell} \cdot w_{\text{ref}}(\text{s})\} = & \left[\frac{(1 - w_{\text{ref}})}{(1 - w_{\text{H}_2\text{O}})} \right] \cdot \left[X\{\text{cell} \cdot w_{\text{H}_2\text{O}}(\text{s})\} - w_{\text{H}_2\text{O}} \cdot X\{\text{H}_2\text{O}(\text{cr, hex})\} \right] \\ & + w_{\text{ref}} \cdot X\{\text{H}_2\text{O}(\text{cr, hex})\}. \end{aligned} \quad (67)$$

The quantity X in eq. (67) can be the standard massic heat capacity $C_{p,w}^\circ$, the standard massic entropy difference $\Delta_0^T S_w^\circ$, the standard massic enthalpy difference $\Delta_0^T H_w^\circ$, or the function Φ_w° at the standard pressure p° and a specified temperature, *e.g.* $T = 298.15$ K. The function Φ_w° is defined as

$$\Phi_w^\circ = \Delta_0^T S_w^\circ - \Delta_0^T H_w^\circ / T. \quad (68)$$

The calculation of values of $\Delta_0^T S_w^*$, $C_{p,w}^*$, $\Delta_0^T H_w^*$, and Φ_w^* for the pure cellulose allomorphs uses the calculated values of $X\{\text{cell}\cdot w_{\text{ref}}(s)\}$ together with the CI values of the samples and follows the treatment given above for the standard massic enthalpies of combustion and solution {see eqs. (25) and (57)}. Then, if one *assumes* that the values of S_w^* at $T = 0$ are equal for the cellulose allomorphs, one can calculate values of $\Delta_r S_w^*$ for reactions (26) to (31).

For the standard molar heat capacity $C_{p,m}^\circ$ of $\text{H}_2\text{O}\{\text{(cr, hex)}\}$, we use a fit done by Juliana Boerio-Goates [J. Boerio-Goates, personal communication] that used property values for $\text{H}_2\text{O}\{\text{(cr, hex)}\}$ from several sources [43-47]. The fit is

$$\begin{aligned} C_{p,m}^\circ = & 0.014C_D(T_D = 55 \text{ K}) + 0.495C_D(T_D = 393 \text{ K}) + 0.05C_E(T_E = 58 \text{ K}) + 0.253C_E(T_E = 103 \text{ K}) \\ & + 0.113C_E(T_E = 325 \text{ K}) + 0.47C_E(T_E = 630 \text{ K}) + 1.615C_E(T_E = 1280 \text{ K}). \end{aligned} \quad (69)$$

The Einstein and Debye heat-capacity functions, respectively, are

$$C_E = 3R \left(\frac{T_E}{T} \right)^2 \frac{e^{-T_E/T}}{(1 - e^{-T_E/T})^2}, \quad (70)$$

$$C_D = 9R \left(\frac{T}{T_D} \right)^3 \int_0^{T_D/T} \frac{x^4 e^x}{(e^x - 1)^2} dx. \quad (71)$$

In the above equations, T_D and T_E are, respectively, the Debye and Einstein temperatures and R is the gas constant ($8.314\,4621 \text{ J}\cdot\text{K}^{-1}\cdot\text{mol}^{-1}$). For $\text{H}_2\text{O}\{\text{(cr, hex)}\}$ at $T = 298.15$ K: $C_{p,m}^\circ = 40.346 \text{ J}\cdot\text{K}^{-1}\cdot\text{mol}^{-1}$; $\Delta_0^T S_m^\circ = 41.546 \text{ J}\cdot\text{K}^{-1}\cdot\text{mol}^{-1}$; $\Delta_0^T H_m^\circ = 6.37782 \cdot 10^3 \text{ J}\cdot\text{mol}^{-1}$; and $\Phi_m^\circ = 20.1547 \text{ J}\cdot\text{K}^{-1}\cdot\text{mol}^{-1}$.

Tables 6 and 7 near here

3.6. Results of combustion experiments

The results of the combustion experiments are shown in table 6. The results in this table are used to calculate values of the standard massic enthalpy of combustion for each combustion experiment (see table 7) as follows:

$$\Delta_c H_w^\circ = \Delta_c U_w^\circ(\text{CO}_2) \cdot m(\text{cell}_{\text{corr}}) / m(\text{cell}). \quad (72)$$

Here, $\Delta_c U_w^\circ(\text{CO}_2)$ is the standard massic energy of combustion based on the mass of CO_2 formed in each experiment, $m(\text{cell}_{\text{corr}})$ is the mass of cellulose corrected for the per cent CO_2 formed, and $m(\text{cell})$ is the mass of cellulose burned in each experiment. Table 7 also gives values of $w_{\text{H}_2\text{O}}$, the total mass fraction of water in the samples based on the mass of $\text{CO}_2(\text{g})$ produced {see eq. (10)}, and $\Delta_c H_w^\circ(w_{\text{ref}} = 0.073)$, the standard massic enthalpy of combustion at the mass fraction of water $w_{\text{ref}} = 0.073$. This latter quantity was calculated by using eqs. (23) and (24).

The average values of $\Delta_c H_w^\circ(w_{\text{ref}} = 0.073)$ for each of the cellulose samples are given in the second column of table 8. As a first step, we use all of the values of $\Delta_c H_w^\circ(w_{\text{ref}} = 0.073)$ obtained for the three different samples of cellulose(am) (*i.e.*, twelve measurements) to obtain the average value $\Delta_c H_w^{\circ*}(w_{\text{ref}} = 0.073) = -(16062 \pm 14) \text{ J} \cdot \text{g}^{-1}$. The “*”, as above, denotes that the sample refers to a pure form of cellulose, which, in this case, is cellulose(am). This pooled value of $\Delta_c H_w^{\circ*}(w_{\text{ref}} = 0.073)$ is used together with the values of $\Delta_c H_w^\circ(w_{\text{ref}} = 0.073)$ obtained for the other cellulose samples (column 2 in table 8) and the values of the crystallinity indexes of the samples (see table 2) to calculate {see eq. (25)} values of $\Delta_c H_w^{\circ*}$, the standard massic enthalpies of combustion of the pure crystalline forms of cellulose I β (cr), cellulose II(cr), and cellulose III(cr). These calculated values are given in the third column in table 8. For cellulose I β (cr), $\Delta_c H_w^{\circ*} = -(16048 \pm 40) \text{ J} \cdot \text{g}^{-1}$. By taking the weighted averages of the respective cellulose II(cr) and cellulose III(cr) samples, the following values are obtained: $\Delta_c H_w^{\circ*} = -(15919 \pm 84) \text{ J} \cdot \text{g}^{-1}$ for cellulose II(cr) and $\Delta_c H_w^{\circ*} = -(16085 \pm 56) \text{ J} \cdot \text{g}^{-1}$ for cellulose III(cr). These values of $\Delta_c H_w^{\circ*}$ are then used to calculate {see eqs. (32) to (37)} values of $\Delta_r H_w^{\circ*}$ for reactions (26) to (31). These values are given in column 3 in table 9.

Tables 8 and 9 near here

We now consider possible systematic errors in the combustion calorimetry measurements. Specifically, we estimate possible inaccuracies in these measurements to be as follows: mass m , $0.0002 \cdot m$; energy equivalent of the calorimeter $\mathcal{E}(\text{calor})$, $0.0002 \cdot \mathcal{E}(\text{calor})$; in the several corrections (fuse, HNO_3 , carbon soot, ignition, and standard state) made to obtain the energy change for the isothermal combustion reaction under actual bomb conditions $\Delta U(\text{IBP})$, $0.0002 \cdot \Delta U(\text{IBP})$; crystallinity index, 0.03 CI ; mass fractions of water $w_{\text{H}_2\text{O}}$ in the samples, $0.0003 \cdot w_{\text{H}_2\text{O}}$; ΔH_{adj} for the adjustment of values of $\Delta_c H_w^\circ$ to $\Delta_c H_w^\circ(w_{\text{H}_2\text{O}} = 0.073)$, $0.20 \cdot \Delta H_{\text{adj}}$; and, for each sample, a possible impurity at a mass fraction $w = 0.005$ having a standard massic energy of combustion 1.25 times that of the cellulose sample. By using propagation of error, we find that the principal source of possible systematic error in the measurements is the possibility of impurities in the cellulose samples. The remaining sources of possible error are negligible in comparison to this possible error. The estimates of possible systematic error are combined in quadrature together with the statistical uncertainties in the previously obtained values of $\Delta_r H_w^\circ$ (see column 3 in table 9), expressed as one-half of the 95 per cent confidence limits, to obtain values of the combined standard uncertainties [48]. These combined standard uncertainties are then multiplied by two to arrive at the expanded uncertainties [48] and final results given in column 4 in table 9.

Table 10 near here

3.7. Results of solution calorimetry experiments

The results of the solution calorimetry experiments are given in table 10. The treatment of results follows the procedure described in section 3.4 above. First, it is noted that the values of $\Delta_{\text{sol}} H_w^\circ(w_{\text{H}_2\text{O}} = 0.073)$ for the three different sample of amorphous (ball-milled cellulose) are in agreement within their uncertainties. The average of the results for the 24 h, 30 h, and 36 h cellulose(am) samples is $\Delta_{\text{sol}} H_w^{\circ*}(w_{\text{H}_2\text{O}} = 0.073) = -(156.1 \pm 2.3) \text{ J} \cdot \text{g}^{-1}$. This value is used together with the values of $\Delta_{\text{sol}} H_w^\circ(w_{\text{H}_2\text{O}} = 0.073)$ for the other samples (see column 4 in table 10) and the values of the crystallinity indexes (see table 2) to calculate, using eqs. (24) and (56), the values of $\Delta_{\text{sol}} H_w^{\circ*}(w_{\text{H}_2\text{O}} = 0.073)$ given in column 5 in table 10. Thus, for cellulose IB(cr), the calculations yield $\Delta_{\text{sol}} H_w^{\circ*}(w_{\text{H}_2\text{O}} = 0.073) = -(49.6 \pm 13) \text{ J} \cdot \text{g}^{-1}$. It is noted that the two values of

$\Delta_{\text{sol}}H_w^{\circ*}(w_{\text{H}_2\text{O}} = 0.073)$ for cellulose II(cr) are not in agreement with each other. Interestingly, the imprecision in the value of $\Delta_{\text{sol}}H_w^{\circ*}(w_{\text{H}_2\text{O}} = 0.073)$ seen in the cellulose II (145 °C) sample data is much smaller than the imprecision in the value of $\Delta_{\text{sol}}H_w^{\circ*}(w_{\text{H}_2\text{O}} = 0.073)$ obtained from the cellulose II (70 °C) sample. Also, the value of $\Delta_{\text{sol}}H_w^{\circ*}(w_{\text{H}_2\text{O}} = 0.073)$ for the cellulose III (-33 °C) sample is not in agreement with the values of $\Delta_{\text{sol}}H_w^{\circ*}(w_{\text{H}_2\text{O}} = 0.073)$ obtained from the other two cellulose III samples, which have values of $\Delta_{\text{sol}}H_w^{\circ*}(w_{\text{H}_2\text{O}} = 0.073)$ that are in good agreement with each other. It is conceivable that these discrepancies might be explained by the large differences in the values of the weight average degree of polymerization DP_w of these cellulose samples. However, the DP_w values for all of the cellulose III samples are very close to each other (see table 3). It is also possible that the fundamental assumption regarding the chemical equivalency of the various forms of cellulose in cadoxen is incorrect. Indeed, based on the NMR spectra (see section 3.2), it is not possible to state with certainty that the various solutions containing cellulose in cadoxen are completely equivalent on a molecular level.

In any case, we proceed with the analysis of the results. The weighted averages of the results from the two cellulose II samples is $\Delta_{\text{sol}}H_w^{\circ*}(w_{\text{H}_2\text{O}} = 0.073) = -(43.0 \pm 7.4) \text{ J}\cdot\text{g}^{-1}$ and the weighted average of the results from the three cellulose III samples is $\Delta_{\text{sol}}H_w^{\circ*}(w_{\text{H}_2\text{O}} = 0.073) = -(41.4 \pm 18) \text{ J}\cdot\text{g}^{-1}$. Note that a weighted average gives little importance to a value that has a much larger uncertainty than the value(s) that have a much lower uncertainty. More importantly, the weighted averages for the cellulose II and cellulose III samples give the greatest weight to those samples having the highest CI values. These values of $\Delta_{\text{sol}}H_w^{\circ*}$ are then used to calculate, using equations analogous to eqs. (32) to (37), values of $\Delta_rH_w^{\circ*}$ for reactions (26) to (31). These values are given in column 3 in table 11.

Table 11 near here

We now consider possible systematic errors in the solution calorimetry measurements. Specifically, we estimate possible inaccuracies in these measurements to be as follows: mass m , $0.002\cdot m$; energy equivalent ε_i , $0.0005\cdot \varepsilon_i$; (ΔH for vaporization of cadoxen + ΔH of sample introduction), 0.10 J ; crystallinity index, $0.03\cdot CI$; $\Delta_{\text{sol}}H_w^{\circ}$ of $\text{H}_2\text{O(l)}$ into cadoxen, $0.24 \text{ J}\cdot\text{g}^{-1}$; mass fractions of water $w_{\text{H}_2\text{O}}$ in the samples, $0.15\cdot w_{\text{H}_2\text{O}}$;

ΔH_{adj} for the adjustment of values of $\Delta_{\text{sol}}H_w^\circ$ to $\Delta_{\text{sol}}H_w^\circ(w_{\text{H}_2\text{O}} = 0.073)$, $0.20 \cdot \Delta H_{\text{adj}}$; and, for each sample, a possible impurity at a mass fraction $w = 0.005$ having a value $\Delta_{\text{sol}}H_w^\circ = 0$. By using propagation of error, we find that the principal source of possible systematic error in the measurements is our knowledge of the crystallinity indexes. This is followed closely by possible errors in the mass fractions of water in the samples and in the adjustment of values of $\Delta_{\text{sol}}H_w^\circ$ to $\Delta_{\text{sol}}H_w^\circ(w_{\text{H}_2\text{O}} = 0.073)$ {see eq. (24)}, and finally to possible impurities in the samples. The remaining sources of possible error are negligible in comparison with the just mentioned sources of possible error. Since the value of $\Delta_{\text{sol}}H_w^{\circ*}$ for cellulose I β (cr) is not too different from the values of $\Delta_{\text{sol}}H_w^{\circ*}$ for cellulose II(cr) and cellulose III(cr), the presence of a small amount of cellulose I β (cr) in either cellulose II(cr) or cellulose III(cr) will cause relatively small errors in the values of $\Delta_{\text{sol}}H_w^{\circ*}$ for these two substances. However, the much more serious concern is the mass fraction of cellulose(am) present in these samples. We note that there are significant differences between the values of $w_{\text{H}_2\text{O}}$ obtained from the combustion results (table 7) and the Karl Fischer analyses (table 4). These differences are very likely attributable to the handling of the samples during the pelleting and in the preparations for the combustion experiments. A similar problem, and a possible source of both random and systematic error, arises in the loading of the glass bulbs used in the solution calorimetry measurements. This problem and the possible errors associated with it could be avoided, albeit with considerable difficulty, by the use of a constant humidity chamber for all sample handling. Alternatively, all of the samples could have been made anhydrous by drying the samples in a vacuum oven at a suitable temperature. However, the removal of the last traces of water, the establishment that one has a truly anhydrous cellulose that is otherwise unchanged, and keeping the samples in their anhydrous states are not trivial matters. Finally, in the absence of a basis for making an error estimate, we choose not to make one for the possible non-equivalence of the different forms of cellulose that have been dissolved in cadoxen. Thus, the estimates of possible systematic error are combined in quadrature together with the statistical uncertainties in the previously obtained values of $\Delta_{\text{r}}H_w^{\circ*}$ (see column 3 in table 11), expressed as one-half of the 95 per cent confidence limits, to obtain values of the combined standard uncertainties [48]. These combined standard

uncertainties are then multiplied by two to arrive at the final expanded uncertainties [48] and results given in column 4 in table 11.

Examination of the results given in tables 9 and 11 shows agreement between the values of $\Delta_r H_w^{\circ*}$ for reactions (27) and (30) based on results obtained from combustion calorimetry and from solution calorimetry. However, the values of $\Delta_r H_w^{\circ*}$ for reactions (26), (28), (29), and (31) are not in agreement. It is worth noting that in the only previous attempt made to use both combustion and solution calorimetry in this way is that of Nelson [14]. In that study [14], the results obtained from the combustion experiments differed by a factor of ten from the results obtained from solution calorimetry experiments. Clearly, the use of combustion calorimetry for this purpose suffers from two difficulties - looking for an accurate value that is a small difference between two large numbers and sensitivity to possible impurities. The principle difficulty with the solution calorimetry is the possible uncertainty due to the possibility of the chemical non-equivalence of the different forms of cellulose after dissolution in cadoxen. Note that the combustion of cellulose in $O_2(g)$ results in the production of $CO_2(g)$ and $H_2O(l)$ and thus not suffer from this concern. However, two additional factors enter into this discussion. Firstly, there is the fact that earlier workers (see section 3.10.2 for a discussion of these literature results) used cupriethylenediamine and ferric sodium tartrate to dissolve cellulose samples and obtained results that are in agreement with results in which cadoxen was used as the solvent. Thus, it is unlikely that three different solvents would each yield essentially the same values for standard massic reaction enthalpies if the dissolved cellulose is chemically non-equivalent. Also, one has a general agreement between the values of $\Delta_r H_w^{\circ*}$ for the mercerization reaction (29) obtained from the solution calorimetry measurements and from earlier measurements [49] that used an alternative approach. Thus, in addition to the facts that the uncertainties in the values of $\Delta_r H_w^{\circ*}$ for reactions (26) to (29) obtained by solution calorimetry are substantially less than those obtained by combustion calorimetry, there are additional facts that support preferring the solution calorimetry results. Nevertheless, the combustion calorimetry results stand on their own as important and useful property values for well characterized cellulose samples.

Tables 12 and 13 and figures 7 and 8 near here

3.8. Results of heat-capacity experiments

The sample masses used for the heat-capacity measurements are given in table 12 and the standard massic heat capacities $C_{p,w}^\circ$ measured with the PPMS are given in table 13 and shown in figures 7 and 8. As can be seen in figure 7, all of the $C_{p,w}^\circ$ curves have inflection points at $T \approx (35, 140, \text{ and } 215) \text{ K}$. Because of these inflection points, the high-temperature ($T > 30 \text{ K}$) and mid-temperature ($10 \text{ K} < T < 45 \text{ K}$) values of $C_{p,w}^\circ$ were fit to orthogonal polynomials:

$$C_{p,w}^\circ = A_0 + A_1T + A_2T^2 + A_3T^3 + A_4T^4 + A_5T^5. \quad (73)$$

The low-temperature values of $C_{p,w}^\circ$ were fit to a sum of theoretical functions that can potentially give information on the lattice, electronic, and magnetic properties of a material:

$$C_{p,w}^\circ = \gamma T + B_3T^3 + B_5T^5 + B_{\text{gap}}T^{3/2}e^{-\delta/T}. \quad (74)$$

In the above equation the T term represents lattice or oxygen vacancies, the T^3 and T^5 terms represent lattice vibrations, and the $T^{3/2}e^{-\delta/T}$ term possibly represents low frequency modes associated with amorphous materials [50-52]. The fitting parameters are given in table 14. Values of $C_{p,w}^\circ$, $\Delta_0^T S_w^\circ$, $\Delta_0^T H_w^\circ$, and Φ_w° have been calculated from the fits at selected temperatures from $T = (0 \text{ to } 300) \text{ K}$. These calculated values of thermodynamic properties for the cellulose samples are given in table 15. It is assumed that the difference $\{C_{p,w}^\circ(p = 0.1 \text{ MPa}) - C_{p,w}^\circ(p = 1.2 \text{ mPa})\}$ is less than $0.001 \cdot C_{p,w}^\circ(p = 0.1 \text{ MPa})$. Thus, no correction is made to the measured $C_{p,w}^\circ$ values for pressure.

Tables 14, 15, and 16 near here

Application of eq. (67) to the values of $C_{p,w}^\circ$, $\Delta_0^T S_w^\circ$, $\Delta_0^T H_w^\circ$, and Φ_w° at $T = 298.15 \text{ K}$ yields values for these properties at $w_{\text{H}_2\text{O}} = 0.073$. These adjusted property values are given in the second part of table 16. Then, use of these adjusted property values and the crystallinity indexes in equations similar to eqs. (25) and (57) leads to the property values given in the third part of table 16. The weighted averages of these property values are given in the fourth part of table 16.

As can be seen in table 14, the root-mean-square (RMS) deviations of the fits are all substantially less than the estimated possible inaccuracies in the calorimetric measurements ($0.02 \cdot C_{p,w}^o$ for $T < 10$ K and $0.01 \cdot C_{p,w}^o$ for $10 \text{ K} < T < 302 \text{ K}$). Thus, we assume that both the random errors and the possible systematic errors in the calorimetric measurements are accounted for by the aforementioned estimates of possible inaccuracies. However, there are additional possible systematic errors in the measurements that must be considered. Specifically, we estimate possible inaccuracies in these measurements to be as follows: mass m , $0.003 \cdot m$; mass fraction of water $w_{\text{H}_2\text{O}}$ in the samples, $0.15 \cdot w_{\text{H}_2\text{O}}$; crystallinity index, $0.03 \cdot CI$; and $C_{p,w}^o(\text{adj})$ for the adjustment of values of $C_{p,w}^o$ to $w_{\text{H}_2\text{O}} = 0.073$, $0.20 \cdot C_{p,w}^o(\text{adj})$. We also estimate a possible mass fraction impurity in the cellulose samples as $w = 0.005$ and that the impurities have a standard massic heat capacity two times the standard massic heat capacities of the respective cellulose samples. These estimates of possible systematic error are used together with the measured values of the heat capacities to perform a propagation of error analysis. The possible errors in the calculated quantities x due to the propagation of each of these possible sources of error are combined in quadrature to calculate combined standard uncertainties $u(x)$. Finally, expanded uncertainties $U(x)$ are estimated by use of the coverage factor, $U(x) = 2u(x)$ [48]. These estimates of error will vary with each individual heat-capacity result and can be propagated to the other property values $\Delta_0^T S_w^o$, $\Delta_0^T H_w^o$, and Φ_w^o . The expanded uncertainties given in table 16 are based on these estimates of possible systematic error. The averages given in the lower part of table 16 were calculated as weighted averages from the results obtained from the respective amorphous cellulose, cellulose II, and cellulose III samples. From the propagation of error analysis, it was found that the principal source of possible error in the measurements is our knowledge of the crystallinity indexes. This is followed closely by possible errors in the mass fractions of water in the samples and in the adjustment of property values to $w_{\text{H}_2\text{O}} = 0.073$, and finally to possible impurities in the samples and in the calorimetric measurements. The remaining sources of possible error are negligible in comparison with the just mentioned sources of possible error.

3.9. Property values for the conversion reactions of the cellulose allomorphs

Table 17 near here

Calculated property values for the conversion reactions of the cellulose allomorphs at $T = 298.15$ K and $p^\circ = 0.1$ MPa are given in table 17. The values of $\Delta_r H_w^*$ in this table are based on the solution calorimetry measurements (see table 11). It is important to recognize that the calculations of the values of the standard massic entropy changes $\Delta_r S_w^*$ and the standard massic Gibbs energy changes $\Delta_r G_w^*$ were made on the *assumption* that the values of S_w^* for all of the allomorphs approach the same value as $T \rightarrow 0$. Since the values of $\Delta_r S_w^*$ and $\Delta_r C_{p,w}^*$ were obtained as differences between values of $\Delta_0^T S_w^*$ and $C_{p,w}^*$ for the respective allomorphs and since these values are very close to each other, the uncertainties in $\Delta_r S_w^*$ and $\Delta_r C_{p,w}^*$ are large. Additionally, the propagation of errors leads to very large uncertainties in the $\Delta_r G_w^*$ values.

There is also the question as to how the thermodynamic property values given in table 17 might vary with degree of polymerization. For reactions in aqueous solution, there is evidence [53] that the dependence of the enthalpy on the degree of polymerization is small for carbohydrates that contain α -1,4 and α -1,6 linkages. However, this matter has not been settled for the solid state. Indeed, to resolve this matter definitively, one would need enthalpy of solution measurements in which samples of a cellulose allomorph having the same respective values of CI and w_{H_2O} , but different values of DP_w , were dissolved in a solvent such as cadoxen. An alternative approach would be to measure standard massic enthalpies of solution $\Delta_{sol} H_w^*$ of cellobiose(cr), cellotriose(cr), cellotetraose(cr), cellopentaose(cr), etc. to see if there is any departure from a constant value of $\Delta_{sol} H_w^*$. This approach is easier, but it is not as definitive as the aforementioned series of suggested measurements. Not considered in the above discussion is the issue of morphology, *i.e.*, the number of cellulose chains in a fibril of a given sample.

The amorphous cellulose samples were prepared by grinding cellulose I β . Since this grinding causes the breaking of hydrogen bonds and a disruption of the hydrophobic and other interactions [16], one expects the crystallization reactions (26), (27), and (28) $\{i.e., \text{cellulose(am)} \rightarrow \text{cellulose (I}\beta, \text{II, and III)(cr)}\}$ to be

exothermic due to the bonded and non-bonded interactions reforming. And, as expected, the values of $\Delta_r H_w^\circ$ for reactions (26), (27), and (28) are all negative. Also, for these same three reactions, the values of $\Delta_r G_w^\circ$ are all negative within their respective combined standard uncertainties. Thus, the aforementioned reactions can, in principle, be used to prepare cellulose (I β , II, and III)(cr) from cellulose(am), which is clearly the least stable of the cellulose allomorphs. In this regard, Hess *et al.* [54] and Hermans and Weidinger [55, 56] reported approximately 70 years ago that cellulose II(cr) could be produced by heating amorphous cellulose with water. More recently, Mittal *et al.* have conducted experiments in which cellulose(am) was converted to cellulose III(cr) [2]. This conversion is accomplished by using anhydrous ammonia [Ashutosh Mittal, personal communication].

Since the values of $\Delta_r G_w^{\circ*}$ for reactions (29), (30), and (31) have large uncertainties, it is not possible to use these values to order quantitatively the relative stabilities of the cellulose (I, II, and III) crystalline allomorphs with a reasonable degree of certainty. However, it is known that cellulose II(cr) can be prepared from cellulose I β (cr) (treatment with NaOH at 25 °C) (see section 2.1). Thus, cellulose II(cr) is more stable than cellulose I β (cr) at $T = 298.15$ K. Also, cellulose III_I(cr) and cellulose III_{II}(cr) can be prepared from cellulose I β and II, respectively, by treatment with liquid ammonia at -75 °C (see section 2.1 and references 2 and 57). Note here that Hayashi *et al.* [57] state that “the crystalline structures of cellulose III derived from cellulose I and from cellulose II are different and should be differentiated from one another as cellulose III_I and cellulose III_{II}, in spite of the fact that they have nearly the same unit cell and equatorial diffractogram.” Thus, if the stability of cellulose III(cr) relative to cellulose I β (cr) and cellulose II(cr) does not depend on temperature over the range -75 °C to 25 °C, the qualitative order of stability for the allomorphs is cellulose III(cr) > cellulose II(cr) > cellulose I β (cr). However, Mittal *et al.* [2] report that cellulose I can be reformed by the application of heat and water to a sample of cellulose III_I. Thus, the difference in the stabilities of the allomorphs cellulose (I, II, and III) appear to be small and may be temperature dependent. The aforementioned order of stability of cellulose I(cr) in regards to

cellulose II(cr) and cellulose III_I(cr) and, in particular, the smallness of the differences is consistent with the results of molecular dynamics simulations by Beckham *et al.* [16]. This discussion of relative stabilities assumes that kinetics do not dominate the molecular events. For example, if Ostwald's rule held for the cellulose allomorphs, nucleation events could run counter to thermodynamic equilibria.

3.10. Comparison with results in literature

3.10.1. Standard massic enthalpies of hydration of the cellulose allomorphs

In order to make comparisons of the property values from our study with those in the literature that pertain to $w_{\text{H}_2\text{O}} = 0$ it is helpful to use a shorthand notation in which the quantity $[\Delta_{\text{hyd}}H_w^\circ\{\text{C}\cdot w_{\text{H}_2\text{O}}(\text{s})\}] - \Delta_{\text{hyd}}H_w^\circ\{\text{C}\cdot w_{\text{H}_2\text{O}}(\text{s})\}]$ (see section 3.3.2) is abbreviated as $\Delta_{\text{hyd}}H_w^\circ(\text{C}, w_i \rightarrow w_f)$. The “C” specifies either the cellulose sample or the pure cellulose allomorph ($CI = 100$), in which case a “*” is also used. The change in the mass fraction of water that occurs due to the hydration (or dehydration) reaction that takes a substance from $w_{\text{H}_2\text{O}i}$ to $w_{\text{H}_2\text{O}f}$ is written as “ $w_i \rightarrow w_f$ ”. And a completely wet sample is designated as “wet”. Thus, the first step in obtaining the values of $\Delta_{\text{hyd}}H_w^{\circ*}(\text{cellulose}, 0 \rightarrow 0.073)$ needed for the comparison of property values is to use the values of $\Delta_{\text{hyd}}H_w^\circ(\text{cellulose sample}, 0 \rightarrow \text{wet})$ that were reported by Nelson [14]. Specifically, she [14] measured standard massic enthalpies of hydration for samples of celluloses (I, II, and III) and for nearly amorphous cellulose along with the CI values for these samples. These anhydrous samples were immersed in 100 cm³ of H₂O(l) and were, presumably, hydrated completely during the course of the solution experiment. The sample of “amorphous” cellulose used by Nelson [14] was prepared by ball milling a sample of cellulose I. The CI value of this nearly amorphous sample was 0.11. Thus, for the hydration of the cellulose I sample, we have the following equation which is analogous to eq. (25)

$$\Delta_{\text{hyd}}H_w^\circ(\text{cell I sample}, 0 \rightarrow \text{wet}) = w_{\text{cr}} \cdot \Delta_{\text{hyd}}H_w^{\circ*}\{\text{cell I}(\text{cr}), 0 \rightarrow \text{wet}\} + (1 - w_{\text{cr}}) \cdot \Delta_{\text{c}}H_w^{\circ*}\{\text{cell}(\text{am}), 0 \rightarrow \text{wet}\}. \quad (75)$$

Equations similar to eq. (75) can be written for the hydration of the cellulose II, cellulose III samples and the nearly amorphous cellulose sample used by Nelson [14] in her study. As done previously, w_{cr} is taken to be equal to $0.01 \cdot CI$. Thus, by using Nelson's [14] values for $\Delta_{\text{hyd}}H_w^\circ(\text{cell samples}, 0 \rightarrow \text{wet})$ and for CI , we now have a system of linear equations of the form of eq. (75). We solve these equations for values of

$\Delta_{\text{hyd}}H_w^{\circ*}(0 \rightarrow \text{wet})$ for the pure cellulose allomorphs. These values of $\Delta_{\text{hyd}}H_w^{\circ*}(0 \rightarrow \text{wet})$ are: $-123 \text{ J}\cdot\text{g}^{-1}$ for cellulose(am), $-28 \text{ J}\cdot\text{g}^{-1}$ for cellulose I(cr), $-22 \text{ J}\cdot\text{g}^{-1}$ for cellulose II(cr), and $-28 \text{ J}\cdot\text{g}^{-1}$ for cellulose III(cr). We note that there is a body of evidence in the literature [15, 58-61] that the absorption of water occurs substantially in the amorphous regions of cellulose samples. Thus, it is of interest that the values of $\Delta_{\text{hyd}}H_w^{\circ*}(0 \rightarrow \text{wet})$ for cellulose I(cr) and cellulose II(cr) are less exothermic than $\Delta_{\text{hyd}}H_w^{\circ*}(0 \rightarrow \text{wet})$ for cellulose(am). However, these values are based entirely on Nelson's [14] very limited data set.

The next step in obtaining values of $\Delta_{\text{hyd}}H_w^{\circ*}(\text{cellulose}, 0 \rightarrow 0.073)$ was to read off values of $\Delta_{\text{hyd}}H_w^{\circ}(0 \rightarrow \text{wet})$ from Rees' [15] figure 4 for the five cellulose samples considered in his study. These samples are (1) cotton, (2) cotton mercerized with tension, (3) cotton mercerized without tension, (4) Fortisan, and (5) Tenasco. Sample 1 consists of {cellulose(am) + cellulose I(cr)} and samples 2, 3, 4, and 5 consist of {cellulose(am) + cellulose II(cr)}. Again, a system of simultaneous linear equations of the form of eq. (75) can be established by using Rees' [15] values of $\Delta_{\text{hyd}}H_w^{\circ}(0 \rightarrow \text{wet})$ and the values of $\Delta_{\text{hyd}}H_w^{\circ*}(0 \rightarrow \text{wet})$ that were calculated above from Nelson's [14] study. Solution of these equations yields *CI* values of 81, 50, 46, 47, and 27 for Rees' [15] cellulose samples 1, 2, 3, 4, and 5, respectively. We then use values of $\Delta_{\text{hyd}}H_w^{\circ}(0 \rightarrow 0.073)$ for these five cellulose samples that are again obtained from Rees' [15] figure 4 together with the calculated *CI* values to set up one more system of linear equations analogous to eq. (75). The solution of these equations gives $\Delta_{\text{hyd}}H_w^{\circ*}(0 \rightarrow 0.073) = -55 \text{ J}\cdot\text{g}^{-1}$ for cellulose(am), $\Delta_{\text{hyd}}H_w^{\circ*}(0 \rightarrow 0.073) = -32 \text{ J}\cdot\text{g}^{-1}$ for cellulose I(cr), and $\Delta_{\text{hyd}}H_w^{\circ*}(0 \rightarrow 0.073) = -44 \text{ J}\cdot\text{g}^{-1}$ for cellulose II(cr). For cellulose III(cr) we estimate $\Delta_{\text{hyd}}H_w^{\circ*}(0 \rightarrow 0.073) = -38 \text{ J}\cdot\text{g}^{-1}$ as the average of the $\Delta_{\text{hyd}}H_w^{\circ*}(w = 0 \rightarrow 0.073)$ values for cellulose I(cr) and cellulose II(cr). These values of $\Delta_{\text{hyd}}H_w^{\circ*}(0 \rightarrow 0.073)$ are estimated to be uncertain by $0.25 \cdot \Delta_{\text{hyd}}H_w^{\circ*}(0 \rightarrow 0.073)$. We use these values of $\Delta_{\text{hyd}}H_w^{\circ*}(0 \rightarrow 0.073)$ in the comparison of property values that follows.

3.10.2. Literature results that lead to values of $\Delta_f H_w^{\circ}$ for reactions (26) to (31)

Table 18 near here

The results of previous studies by Calvet and Hermans [63], Nelson [14], and Dale and Tsao [64] for reactions (26), (27), and (28), all of which refer to $w_{\text{H}_2\text{O}} = 0$, are shown in table 18. Comparisons of these results with those obtained in this study that pertain to $w_{\text{H}_2\text{O}} = 0.073$ can be made by using the values of $\Delta_{\text{hyd}}H_w^{\circ*}(0 \rightarrow 0.073)$ given in section 3.10.1 and a thermochemical cycle calculation. Thus, for reaction (26)

$$\Delta_r H_w^{\circ*}(w_{\text{H}_2\text{O}} = 0) = \Delta_r H_w^{\circ*}(w_{\text{H}_2\text{O}} = 0.073) + \Delta_{\text{hyd}}H_w^{\circ*}\{\text{cell(am)}, 0 \rightarrow 0.073\} - \Delta_{\text{hyd}}H_w^{\circ*}\{\text{cell I(cr)}, 0 \rightarrow 0.073\}. \quad (76)$$

Analogous equations hold for reactions (27), (28), (29), (30), and (31). The values of $\Delta_r H_w^{\circ*}(w_{\text{H}_2\text{O}} = 0)$ calculated from our values of $\Delta_r H_w^{\circ*}(w_{\text{H}_2\text{O}} = 0.073)$ are also shown in table 18. These values are seen to be more exothermic for reactions (26) and (28) than the earlier studies. However, all values for reactions (26), (27), and (28) are in agreement within their uncertainties. Values of $\Delta_r H_w^{\circ*}$ for the mercerization reaction (29) are also summarized in table 18. Our result is in agreement with the values of $\Delta_r H_w^{\circ*}$ obtained from the studies of Calvet [62], Ranby [49], Nelson [14], and Dale and Tsao [64]. The value of $\Delta_r H_w^{\circ*}$ for reaction (29) calculated from the study of Ioelovich [75] appears to be an outlier.

Nelson [14] also measured (see pages 44 and 45 in her thesis) the standard massic enthalpies of combustion $\Delta_c H_w^{\circ}$ of samples of cellulose I, cellulose II, and cellulose III. She [14] used two different samples of cellulose I having respective *CI* values of 87.8 and 93.4, which were measured by using acid hydrolysis. The values of $\Delta_c H_w^{\circ}$ and *CI* for these two samples were then used to calculate values of $\Delta_c H_w^{\circ*}$ for cellulose(am) and for cellulose I(cr). By using her [14] measured values of *CI* for the cellulose II and cellulose III samples, she [14] then calculated values of $\Delta_c H_w^{\circ*}$ for cellulose II(cr) and cellulose III(cr). Her [14] results (see pages 77 and 78 in her thesis) were: $\Delta_c H_w^{\circ*} = -18376 \text{ J}\cdot\text{g}^{-1}$ for cellulose(am); $\Delta_c H_w^{\circ*} = -17330 \text{ J}\cdot\text{g}^{-1}$ for cellulose I(cr); $\Delta_c H_w^{\circ*} = -17125 \text{ J}\cdot\text{g}^{-1}$ for cellulose II(cr); and $\Delta_c H_w^{\circ*} = -17205 \text{ J}\cdot\text{g}^{-1}$ for cellulose III(cr). These results were then used to calculate the following values: $\Delta_r H_w^{\circ*} = -1046 \text{ J}\cdot\text{g}^{-1}$ for reaction (26); $\Delta_r H_w^{\circ*} = -1251 \text{ J}\cdot\text{g}^{-1}$ for reaction (27); and $\Delta_r H_w^{\circ*} = -1172 \text{ J}\cdot\text{g}^{-1}$ for reaction (28). It is seen that the results obtained by use of Nelson's [14] combustion experiments differ by a factor of ten from the results obtained by her [14] from her solution calorimetry experiments (see table 18). This very large discrepancy

may be due to the fact that the two samples of cellulose I that she used had CI values that were too close together, making the extrapolation to a value of $\Delta_c H_w^{\circ*}$ for cellulose(am) very uncertain. This large discrepancy may have also caused Nelson to forego journal publication of her important work. The results of Nelson [14] are discussed further below in conjunction with other values of $\Delta_c H_w^{\circ}$ for cellulose from the literature.

A complication that arises in the comparison of property values is the fact that there are two forms of cellulose I, *i.e.*, cellulose I α and cellulose I β . Cellulose I α is produced by bacteria and algae, while cellulose I β is the predominant form found in plants [3]. Thus, while essentially all of the previous studies in which thermodynamic property values were reported did not state which form of cellulose I they used, most of these studies identified the source of the cellulose I that they used to be from plants and in no case was the cellulose identified as having been produced by bacteria or algae. Thus, it is highly likely that cellulose I β was the predominant form used in the studies with which comparisons of results are made. Nevertheless, it is likely that many of the samples of cellulose I β used in these studies were cellulose I α [4, 76].

Table 19 near here

3.10.3. Literature results for the standard massic enthalpies of combustion

Results from the literature for the standard massic enthalpies of combustion $\Delta_c H_w^{\circ}$ of samples of cellulose in oxygen {reaction (9)} are shown in table 19. We first consider the measured values of $\Delta_c H_w^{\circ}$ for cellulose I samples. Ioelovich *et al.* [85], Ur'yash *et al.* [88], and Blokhin *et al.* [89] measured values of $\Delta_c H_w^{\circ}$ for cellulose I samples at various CI values. By fitting their respective values of $\Delta_c H_w^{\circ}$ vs CI and extrapolating to $CI = 100$, the results reported by Ioelovich *et al.* [85], by Ur'yash *et al.* [88], and by Blokhin *et al.* [89] lead, respectively, to $\Delta_c H_w^{\circ*} = -17337 \text{ J}\cdot\text{g}^{-1}$, $\Delta_c H_w^{\circ*} = -17458 \text{ J}\cdot\text{g}^{-1}$, and $\Delta_c H_w^{\circ*} = -17165 \text{ J}\cdot\text{g}^{-1}$ for cellulose I(cr). The earlier, very carefully done measurements of Jessup and Prosen [80] and Colbert *et al.* [84] did not include a measurement of CI but the samples that they used probably had high CI values. We use the value

$\Delta_r H_w^\circ = -113 \text{ J}\cdot\text{g}^{-1}$ for reaction (26) {this is the average of the values of $\Delta_r H_w^\circ$ for reaction (26) at $w = 0$; see table 18} and assume that the cellulose samples used by Jessup and Prosen [80] and by Colbert *et al.* [84] had CI values of ≈ 75 . This assumption gives an adjustment of $-(0.25 \times -113 \text{ J}\cdot\text{g}^{-1}) = 28 \text{ J}\cdot\text{g}^{-1}$ to be applied to the values of $\Delta_c H_w^\circ$ obtained by Jessup and Prosen [80] and by Colbert *et al.* [84]. Note that $\Delta_c H_w^{\circ*}$ for cellulose(am) is more exothermic than $\Delta_c H_w^{\circ*}$ for cellulose I (cr). Hence, the sign of the $28 \text{ J}\cdot\text{g}^{-1}$ adjustment is positive. Applying these corrections, one obtains $\Delta_c H_w^{\circ*} = -17421 \text{ J}\cdot\text{g}^{-1}$ and $\Delta_c H_w^{\circ*} = -17317 \text{ J}\cdot\text{g}^{-1}$ for cellulose I(cr) from the respective studies of Jessup and Prosen [80] and Colbert *et al.* [84]. Applying a similar correction to Nelson's [14] results, one obtains $\Delta_c H_w^{\circ*} = -17414 \text{ J}\cdot\text{g}^{-1}$ for cellulose I(cr). In making the adjustment to Nelson's [14] values of $\Delta_c H_w^\circ$ for the two samples of cellulose I(cr), we used the respective averages of her [14] reported CI values that are based on acid hydrolysis and XRD. All of these values pertain to $T = 298.15 \text{ K}$ and $w_{\text{H}_2\text{O}} = 0$. The average of the results obtained from five studies [14, 80, 84, 85, 88] is $\Delta_c H_w^{\circ*} = -(17390 \pm 54) \text{ J}\cdot\text{g}^{-1}$. Here, the uncertainty is equal to two estimated standard deviations of the mean. The value of $\Delta_c H_w^{\circ*} = -17165 \text{ J}\cdot\text{g}^{-1}$ from Blokhin *et al.* [89] is an outlier and was not used in calculating the average. From our study, we have $\Delta_c H_w^{\circ*} = -(16048 \pm 40) \text{ J}\cdot\text{g}^{-1}$ for cellulose I(cr) (see table 8) that pertains to $T = 298.15 \text{ K}$ and $w_{\text{H}_2\text{O}} = 0.073$. We use eq. (23) together with our measured value of $\Delta_c H_w^{\circ*}(w_{\text{H}_2\text{O}} = 0.073)$ for cellulose I(cr) and the value $\Delta_{\text{hyd}} H_w^{\circ*}(0 \rightarrow 0.073) = -32 \text{ J}\cdot\text{g}^{-1}$ for cellulose I(cr) and calculate $\Delta_c H_w^{\circ*} = -(17344 \pm 41) \text{ J}\cdot\text{g}^{-1}$ for $w_{\text{H}_2\text{O}} = 0$. This value is in agreement with the value $\Delta_c H_w^{\circ*} = -(17390 \pm 54) \text{ J}\cdot\text{g}^{-1}$ for cellulose I(cr) obtained from what appear to be the best of the studies in the literature.

Nelson [14] and Ioeleovich *et al.* [85] report values of $\Delta_c H_w^\circ$ and CI for cellulose II samples. We adjust their [14, 85] reported values to $CI = 100$ using the same methods used for treating the $\Delta_c H_w^\circ$ values for the cellulose I samples and obtain $\Delta_c H_w^{\circ*} = -(17354 \pm 11) \text{ J}\cdot\text{g}^{-1}$ and $\Delta_c H_w^{\circ*} = -(17337 \pm 12) \text{ J}\cdot\text{g}^{-1}$ for cellulose II(cr) from these two respective studies. As above, we use our measured value for $\Delta_c H_w^{\circ*}(w_{\text{H}_2\text{O}} = 0.073)$ with eq. (23) and with $\Delta_{\text{hyd}} H_w^{\circ*}(0 \rightarrow 0.073) = -44 \text{ J}\cdot\text{g}^{-1}$ to calculate $\Delta_c H_w^{\circ*} = -(17217 \pm 85) \text{ J}\cdot\text{g}^{-1}$ for cellulose II(cr) at $w_{\text{H}_2\text{O}} = 0$. Both Nelson's [57] and Ioeleovich's [85] uncertainties are very optimistic and do not

include any possible systematic errors. Thus, it is likely that all three values of $\Delta_c H_w^{\circ*}$ for cellulose II(cr) are in agreement.

The only value of $\Delta_c H_w^{\circ}$ in the literature for a cellulose III sample comes from the study of Nelson [14]. As above, we adjust her [14] reported value of $\Delta_c H_w^{\circ}$ to $CI = 100$ and obtain $\Delta_c H_w^{\circ*} = -(17359 \pm 18) \text{ J}\cdot\text{g}^{-1}$ for cellulose III(cr). Adjustment of our measured value for $\Delta_c H_w^{\circ*}(w_{\text{H}_2\text{O}} = 0.073)$ to $w = 0$ {eq. (23) with $\Delta_{\text{hyd}} H_w^{\circ*}(0 \rightarrow 0.073) = -38 \text{ J}\cdot\text{g}^{-1}$ } leads to $\Delta_c H_w^{\circ*} = -(17390 \pm 57)$. The two values of $\Delta_c H_w^{\circ*}$ for cellulose III(cr) are in good agreement.

There are two direct measurements of $\Delta_c H_w^{\circ*}$ for cellulose(am) in the literature: $\Delta_c H_w^{\circ*} = -(17548 \pm 27) \text{ J}\cdot\text{g}^{-1}$ from Ur'yash *et al.* [88] and $\Delta_c H_w^{\circ*} = -(16980 \pm 50) \text{ J}\cdot\text{g}^{-1}$ from Blokhin *et al.* [89]. Additionally, extrapolation of the $\Delta_c H_w^{\circ}$ values for the cellulose I and cellulose II samples from the study of Ioelovich *et al.* [85] to $CI = 0$ gives $\Delta_c H_w^{\circ*} = -17561 \text{ J}\cdot\text{g}^{-1}$ for cellulose(am). All three values of $\Delta_c H_w^{\circ*}$ pertain to $w_{\text{H}_2\text{O}} = 0$. Again we adjust our measured value for $\Delta_c H_w^{\circ*}(w_{\text{H}_2\text{O}} = 0.073)$ to $w_{\text{H}_2\text{O}} = 0$ {eq. (23) with $\Delta_{\text{hyd}} H_w^{\circ*} = -55 \text{ J}\cdot\text{g}^{-1}$ } and obtain $\Delta_c H_w^{\circ*} = -(17382 \pm 20) \text{ J}\cdot\text{g}^{-1}$, a value that is in the range of the aforementioned values from the literature. Nelson's [14] long extrapolation of her $\Delta_c H_w^{\circ}$ values for cellulose (I, II, and III) samples to $CI = 0$ led to $\Delta_c H_w^{\circ*} = -18376 \text{ J}\cdot\text{g}^{-1}$ for cellulose(am). This value is an outlier. The values of $\Delta_c H_w^{\circ*}(w_{\text{H}_2\text{O}} = 0)$ for cellulose(am), cellulose I(cr), cellulose II(cr), and cellulose III(cr) are summarized in table 20.

Tables 20 and 21 near here

3.10.4. Literature results for standard massic heat capacities and derived thermal functions

Results from the literature pertinent to the standard massic heat capacities $C_{p,w}^{\circ}$ and the thermodynamic properties derived from these measured values are shown in table 21. Note that for two studies (Kozolv *et al.* [96] and Ur'yash *et al.* [88]), we calculated the values of $\Delta_0^T S_w^{\circ}$ and $\Delta_0^T H_w^{\circ}$ from the reported results by using a Hermite polynomial fit (*Mathematica* function “Interpolation”) of the $C_{p,w}^{\circ}$ values and an empirical extrapolation to $T = 0$ followed by the necessary integrations. One sees from table 21 that there are four

previous studies {Kozolv *et al.* [96], Hatakema *et al.* [99], Mochalov *et al.* [101], and Blokhin *et al.* [89]} where standard massic heat capacities were measured on cellulose samples and where *CI* values are also known. In three of these studies [89, 99, 101], the results cover a sufficient range of *CI* values and have a precision sufficient to permit a reasonable extrapolation of measured property values with *CI* and calculation of thermodynamic property values for cellulose(am) and cellulose I(cr). The results of these calculations are also shown in table 21.

Values of $C_{p,w}^{\circ*}$, $\Delta_0^T S_w^{\circ*}$, $\Delta_0^T H_w^{\circ*}$, and $\Phi_w^{\circ*}$ for the anhydrous ($w_{H_2O} = 0$) pure cellulose allomorphs can be calculated from our measured values of these quantities that pertain to $w_{H_2O} = 0.073$. This is done by setting w_{ref} equal to zero in eq. (67) to give

$$X\{\text{anhydrous cellulose}\} = (1 - w_{H_2O})^{-1} \cdot [X\{\text{cell} \cdot w_{H_2O}(s)\} - w_{H_2O} \cdot X\{H_2O(cr, hex)\}]. \quad (77)$$

We shall assume that this adjustment of the property values to $w_{H_2O} = 0$ is uncertain by 25 per cent. The adjusted property values are shown in table 22. The comparison of our results with those obtained from the literature cannot be certain due to the fact that uncertainties were not assigned to the property values in the previous studies [89, 99, 101]. Nevertheless, one sees that the value of $C_{p,w}^{\circ*}$ for cellulose(am) and for cellulose I β (cr) from Hatakema *et al.* [99], who used DSC in their study, are outliers. Also, the values of $C_{p,w}^{\circ*}$ for cellulose I β (cr) are most likely in agreement. But our value of $C_{p,w}^{\circ*}$ for cellulose(am) most likely differs from the values obtained from the studies of Mochalov *et al.* [101] and Blokhin *et al.* [89]. Most importantly, all of the values of $\Delta_0^T S_w^{\circ*}$, $\Delta_0^T H_w^{\circ*}$, and $\Phi_w^{\circ*}$ at $T = 298.15$ K and $w_{H_2O} = 0$ for both cellulose(am) and cellulose I β (cr) are in agreement or near agreement.

Tables 22 and 23 near here

Then, by using these values, we calculate values of $\Delta_r S_w^{\circ*}$ and $\Delta_r C_{p,w}^{\circ*}$ for the reaction {cellulose(am) = cellulose I(cr)}, reaction (26), at $T = 298.15$ K. These calculated values are shown in table 23. One sees that our values for $\Delta_r S_w^{\circ*}$ and for $\Delta_r C_{p,w}^{\circ*}$ at $w_{H_2O} = 0$ are in agreement with the results obtained from Mochalov *et al.* [101] and from Blokhin *et al.* [89]. The value of $\Delta_r C_{p,w}^{\circ*}$ for cellulose(am) and for cellulose I(cr) calculated from the study of Hatakema *et al.* [99] is again an outlier. The results presented in this study

appear to be the first thermal property measurements on samples of cellulose II and cellulose III. We are not aware of any measurements of thermodynamic property values for cellulose IV.

3.11. Calculation of standard formation properties

The calculation of the standard formation properties of the cellulose allomorphs relies to a large extent on the value of $\Delta_c H_w^\circ\{\text{cellulose } w_{\text{ref}}(\text{am})\} = -(16062 \pm 14) \text{ J} \cdot \text{g}^{-1}$ (see table 8). This value is used in preference to the values of $\Delta_c H_w^\circ$ for the other allomorphs due to the fact that the uncertainty in this value is much less than the uncertainties in these other values of $\Delta_c H_w^\circ$. Auxiliary data used in these calculations are the standard molar enthalpies of formation $\Delta_f H_m^\circ\{\text{H}_2\text{O}(\text{l})\} = -(285.830 \pm 0.040) \text{ kJ} \cdot \text{mol}^{-1}$ and $\Delta_f H_m^\circ\{\text{CO}_2(\text{g})\} = -(393.51 \pm 0.13) \text{ kJ} \cdot \text{mol}^{-1}$ from the CODATA Tables [102]. These calculations are conveniently done by using molar properties. Thus, we use eqs. (3) and (6) together with an assumed value $u = 300$, which is close to the average value $\langle DP_w \rangle = 313$ (see table 3), and $w_{\text{H}_2\text{O}} = 0.073$ to solve the aforementioned equations and obtain $M_r = 5.24728 \cdot 10^4$ and $v = 211.629$. Thus, by using the combustion reaction (1) and the aforementioned values for $\Delta_f H_m^\circ\{\text{H}_2\text{O}(\text{l})\}$ and for $\Delta_f H_m^\circ\{\text{CO}_2(\text{g})\}$, we calculate $\Delta_f H_m^\circ\{\text{cellulose } w_{\text{ref}}(\text{am})\} = -(355.02 \pm 0.77) \text{ MJ} \cdot \text{mol}^{-1}$, where $w_{\text{ref}} = w_{\text{H}_2\text{O}} = 0.073$. Then, the standard massic enthalpy of formation $\Delta_f H_w^\circ\{\text{cellulose } w_{\text{ref}}(\text{am})\}$ is calculated by dividing $\Delta_f H_m^\circ\{\text{cellulose } w_{\text{ref}}(\text{am})\}$ by M_r . Since the value of $\Delta_f H_m^\circ\{\text{cellulose } w_{\text{ref}}(\text{am})\}$ depends on the assumed value of u , it is convenient to have a value of $\Delta_f H_u^\circ$ (the subscript “u” denotes the monomer unit) that pertains to the hydrated cellulose monomer unit $\text{C}_6\text{H}_{10}\text{O}_5$. A value for $\Delta_f H_u^\circ\{\text{cellulose } w_{\text{ref}}(\text{am})\}$ is readily obtained either by dividing $\Delta_f H_m^\circ\{\text{cellulose } w_{\text{ref}}(\text{am})\}$ by u or by multiplying $\Delta_f H_w^\circ$ by the value of M_r for the monomer unit. This latter calculation is very accurate when a large value of u is used.

The calculation of values of $\Delta_f H_m^\circ$ for the cellulose allomorphs I, II, and III uses the value of $\Delta_c H_w^\circ\{\text{cellulose } w_{\text{ref}}(\text{am})\}$ calculated above together with the values of $\Delta_r H_w^{\circ*}$ for reactions (26), (27), and (28) (see table 11) to calculate values of $\Delta_c H_w^\circ\{\text{cellulose } w_{\text{ref}}\}$ for these three allomorphs. This provides one set of values of $\Delta_c H_w^\circ$ for these three allomorphs. However, we also have a set of directly measured values of

$\Delta_c H_w^\circ\{\text{cellulose } w_{\text{ref}}\}$ (see table 8) for these three allomorphs. Thus, we calculate the respective weighted averages of these values to obtain a “best” set of values for $\Delta_c H_w^\circ$ for the cellulose allomorphs:

$$\Delta_c H_w^\circ\{\text{cellulose I(cr)} w_{\text{ref}}\} = -(15979 \pm 20) \text{ J} \cdot \text{g}^{-1}, \Delta_c H_w^\circ\{\text{cellulose I(cr)} w_{\text{ref}}\} = -(15948 \pm 17) \text{ J} \cdot \text{g}^{-1}, \text{ and}$$

$\Delta_c H_w^\circ\{\text{cellulose I(cr)} w_{\text{ref}}\} = -(15969 \pm 22) \text{ J} \cdot \text{g}^{-1}$. The calculation of values of $\Delta_f H_m^\circ\{\text{cellulose } w_{\text{ref}}\}$ for the cellulose allomorphs I, II, and III follows the procedure described above to calculate

$\Delta_f H_m^\circ\{\text{cellulose } w_{\text{ref}}(\text{am})\}$. These calculated values are given in table 24.

Tables 24 near here

In the calculations that follow, *it is assumed* that the value of S_w° for each of the cellulose allomorphs is equal to the respective measured value of $\Delta^\dagger S_w^\circ$, *i.e.*, $S_w^\circ \rightarrow 0$ as $T \rightarrow 0$ for each allomorph. In principle, if one had detailed structural information on the cellulose allomorphs, one could calculate the thermodynamic probability W [103, 104] for a mole of each of the allomorphs. In turn, this would allow for the calculation of the residual molar entropies $S_m^\circ(T \rightarrow 0)$ by use of the Boltzmann equation

$$S_m^\circ = R \ln W. \quad (78)$$

As an example, we use the value $W = 6 \cdot 10^{23}$ and calculate $S_m^\circ = 455 \text{ J} \cdot \text{K}^{-1} \cdot \text{mol}^{-1}$. However for a substance having a relative molecular mass $M_r = 5 \cdot 10^4$, one obtains $S_w^\circ = 0.009 \text{ J} \cdot \text{K}^{-1} \cdot \text{g}^{-1}$, which is still a very small uncertainty in the value of S_w° . In any case, we do not have the structural information and we do not know W . Also, the calculation of the values of W , even if the crystal structures of the cellulose allomorphs were completely determined, would not be a trivial matter.

In any case, we now consider the formation reaction for one mole of cellulose(am), namely

First, a value of the standard molar entropy $S_m^\circ\{\text{cellulose } w_{\text{ref}}\}$ for all four cellulose allomorphs is obtained by multiplying the values of $S_w^\circ\{\text{cellulose } w_{\text{ref}}\}$ by the calculated value of M_r . Then, by using the CODATA [102] values $S_m^\circ\{\text{C(s)}\} = (5.74 \pm 0.10) \text{ J} \cdot \text{K}^{-1} \cdot \text{mol}^{-1}$, $S_m^\circ\{\text{H}_2(\text{g})\} = (130.680 \pm 0.003) \text{ J} \cdot \text{K}^{-1} \cdot \text{mol}^{-1}$, and $S_m^\circ\{\text{O}_2(\text{g})\}$

$= (209.152 \pm 0.005) \text{ J} \cdot \text{K}^{-1} \cdot \text{mol}^{-1}$, we calculate the standard molar entropies of formation $\Delta_f S_m^\circ\{\text{cellulose } w_{\text{ref}}\}$.

These values of $\Delta_f S_m^\circ\{\text{cellulose } w_{\text{ref}}\}$ are then combined with the previously calculated values of $\Delta_f H_m^\circ\{\text{cellulose } w_{\text{ref}}\}$ to yield values for $\Delta_f G_m^\circ\{\text{cellulose } w_{\text{ref}}\}$. Then, as above, values of massic quantities are obtained by dividing the molar quantities by M_r and property values for the monomer unit are obtained by dividing the molar quantities by u . These calculated values are also given in table 24. Note that we used an assumed value $u = 300$ in performing these calculations. However, the use of $u = 1000$ in these calculations yields identical values of thermodynamic properties to within the number of digits shown in table 24.

Values of the standard formation properties of the anhydrous cellulose allomorphs are obtained by first using the “best” set of values of $\Delta_c H_w^\circ\{\text{cellulose } w_{\text{ref}}\}$ (see above) together with the values of $\Delta_{\text{hyd}} H_w^\circ\{\text{cellulose } w_{\text{ref}}, 0 \rightarrow w_{\text{ref}}\}$ obtained previously (see section 3.10.1) to calculate values of $\Delta_c H_w^\circ\{\text{cellulose } w=0\}$. These values are, in turn, used to calculate values of $\Delta_f H_w^\circ\{\text{cellulose } w=0\}$ by using the same procedure (see above) that was used to calculate values of $\Delta_f H_w^\circ\{\text{cellulose } w_{\text{ref}}\}$. The values of $\Delta_f H_u^\circ\{\text{cellulose } w=0\}$ that pertain to the anhydrous monomer unit were calculated by multiplying the corresponding values of $\Delta_f H_w^\circ\{\text{cellulose } w=0\}$ by the value of M_r for the anhydrous monomer unit $\text{C}_6\text{H}_{10}\text{O}_5$. The massic entropies for the anhydrous cellulose allomorphs (see table 22) were used to calculate values of $\Delta_f S_m^\circ$ as was done above for the hydrated samples. These values of $\Delta_f S_m^\circ\{\text{cellulose } w=0\}$ were then combined with the corresponding values of $\Delta_f H_m^\circ\{\text{cellulose } w=0\}$ to calculate values of $\Delta_f G_m^\circ\{\text{cellulose } w=0\}$. The values of S_w° and $C_{p,w}^\circ$ given in in table 24 were taken either from table 16 (allomorphs having $w_{\text{H}_2\text{O}} = 0.073$) or from table 22 (allomorphs having $w_{\text{H}_2\text{O}} = 0$) and which are all based on our results. *It is important to note the following items.* If our assumption regarding the equality of S_w° to $\Delta_0 S_w^\circ$ is in error, the true values of $\Delta_f S_w^\circ$ and $\Delta_f S_u^\circ$ will be less than (more negative) than the values given in table 24. Also, the true values of $\Delta_f G_w^\circ$ and $\Delta_f G_u^\circ$ will be greater than (more positive) than the tabulated

values. Similar considerations apply to the values of $\Delta_r S_w^\circ$ and $\Delta_r G_w^\circ$ given in tables 17 and 23. Clearly the values of the enthalpies and heat capacities are not affected by this assumption.

3.12. Thermodynamic property values for the conversion of the cellulose allomorphs to α -D-glucose(cr)

Considering the practical importance of converting cellulose to glucose, it is of interest to calculate the thermodynamic properties for the conversion reaction

Here, $(\text{C}_6\text{H}_{10}\text{O}_5)_u \cdot (\text{H}_2\text{O})_1 \cdot (\text{H}_2\text{O})_v(\text{s})$ represents either cellulose(am), cellulose I(cr), cellulose II(cr), or cellulose III(cr), and $\text{C}_6\text{H}_{12}\text{O}_6(\text{cr})$ is α -D-glucose(cr). The standard formation properties for the cellulose allomorphs were calculated above and are given in table 24. From the literature we have the following property values for α -D-glucose(cr): $\Delta_f H_m^\circ = -(1273.04 \pm 0.87) \text{ kJ} \cdot \text{mol}^{-1}$ [105], $S_m^\circ = (209.2 \pm 0.4) \text{ J} \cdot \text{K}^{-1} \cdot \text{mol}^{-1}$ [106], and $C_{p,m}^\circ = (219.2 \pm 0.4) \text{ J} \cdot \text{K}^{-1} \cdot \text{mol}^{-1}$ [106]. Using these property values and the standard molar entropies of C(cr), $\text{H}_2(\text{g})$, and $\text{O}_2(\text{g})$ [102], we calculate $\Delta_f G_m^\circ = -(907.87 \pm 0.88) \text{ kJ} \cdot \text{mol}^{-1}$ for α -D-glucose(cr). The only additional auxiliary data required to calculate the thermodynamic properties for the conversion reactions (80), and not given above, are: $C_{p,w}^\circ\{\text{H}_2\text{O}(\text{l})\} = 75.291 \text{ J} \cdot \text{K}^{-1} \cdot \text{mol}^{-1}$ [107], $S_m^\circ\{\text{H}_2\text{O}(\text{l})\} = (69.95 \pm 0.03) \text{ J} \cdot \text{K}^{-1} \cdot \text{mol}^{-1}$ [102], and $\Delta_f G_m^\circ\{\text{H}_2\text{O}(\text{l})\} = -(237.140 \pm 0.041) \text{ kJ} \cdot \text{mol}^{-1}$ [102]. The calculations of the reaction quantities are, as was done for the standard formation properties, most conveniently carried out on a molar basis. Here, we again use an assumed value of u , *i.e.*, $u = 300$, to calculate M_r which is then used to multiply the standard massic formation properties given in table 24 to give the desired standard molar formation properties for the cellulose allomorphs. Then, with a knowledge of the state of hydration, *i.e.* the value of v (see section 3.11), one calculates the reaction quantities on a molar basis. These molar values are then easily converted to a massic basis (division of the molar quantity by M_r) and a monomer unit basis (division of the molar quantity by u). We note that the calculated property values given in table 25 do not depend on the value of u . *It is important to note the following items.* If our assumption regarding the equality of S_w° to $\Delta_0^T S_w^\circ$ is in error, the true values of $\Delta_r S_w^\circ$ and $\Delta_r S_u^\circ$ will be less than (more negative) than the values given in table 24. Also, the true values of $\Delta_r G_w^\circ$ and $\Delta_r G_u^\circ$ will be greater

than (more positive) than the tabulated values. The property values given in tables 24 and 25 pertain to $w_{\text{H}_2\text{O}} = 0$ and $w_{\text{H}_2\text{O}} = 0.073$.

For comparison with the above property values for reaction (80), we consider the reaction

which, in fact, is reaction (80) for $u = 2$ and $v = 0$. By using the standard formation properties for cellobiose(cr) given by Tewari *et al.* [108] we calculate $\Delta_r H_m^\circ = -17.2 \text{ kJ}\cdot\text{mol}^{-1}$, $\Delta_r G_m^\circ = -0.1 \text{ kJ}\cdot\text{mol}^{-1}$, and $\Delta_r S_m^\circ = -57.4 \text{ J}\cdot\text{K}^{-1}\cdot\text{mol}^{-1}$ for reaction (81) at $T = 298.15 \text{ K}$. As a comparison, the reaction of cellobiose(aq) to $\alpha\text{-D-glucose}(\text{aq})$ is

for which the standard reaction quantities are $\Delta_r H_m^\circ = -2.4 \text{ kJ}\cdot\text{mol}^{-1}$, $\Delta_r G_m^\circ = -16.1 \text{ kJ}\cdot\text{mol}^{-1}$, and $\Delta_r S_m^\circ = 46.0 \text{ J}\cdot\text{K}^{-1}\cdot\text{mol}^{-1}$ at $T = 298.15 \text{ K}$ [108]. It is seen that reaction (82) is driven largely by a positive value of $\Delta_r S_m^\circ$. Also, there is very good evidence [53, 108] that the values of $\Delta_r H_m^\circ$, $\Delta_r G_m^\circ$, and $\Delta_r S_m^\circ$ for reaction (82) will also hold for the similar hydrolysis reactions of larger cello-oligomers, *e.g.*

On a massic basis, the property values for reaction (81) are $\Delta_r H_w^\circ = -50.3 \text{ J}\cdot\text{g}^{-1}$, $\Delta_r G_w^\circ = -0.3 \text{ J}\cdot\text{g}^{-1}$, and $\Delta_r S_w^\circ = -0.13 \text{ J}\cdot\text{K}^{-1}\cdot\text{g}^{-1}$. These values can be compared with the values for anhydrous cellulose(am) given in table 25. Note that the value $\Delta_r H_w^\circ = -50.3 \text{ J}\cdot\text{g}^{-1}$ for reaction (81) is less exothermic than the value $\Delta_r H_w^\circ = -101 \text{ J}\cdot\text{g}^{-1}$ for cellulose(am), but more exothermic than the values of $\Delta_r H_w^\circ$ for the other cellulose allomorphs (see table 25). Indeed, all of the values of $\Delta_r H_w^\circ$ are endothermic for all of the cellulose allomorphs with the exception of cellulose(am). This is consistent with the view that the hydrogen bonding along with the hydrophobic and other interactions have been destroyed by ball-milling during the preparation of cellulose(am) and that there is additional bonded and non-bonded interactions in the other cellulose allomorphs. Of particular interest is

the fact that the conversion reactions for the cellulose allomorphs, with the exception of anhydrous cellulose(am), all have positive values of $\Delta_r G_w^\circ$ and thus are thermodynamically not favored. This conclusion is not invalidated by our assumption regarding the equality of S_w° to $\Delta_0^T S_w^\circ$.

In terms of “energy cost”, cellulose(am) is the least expensive and the cellulose (I, II, and III) crystalline allomorphs are the most expensive to convert to α -D-glucose(cr). This conclusion is valid for cellulose allomorphs having mass fractions of water less than or equal to $w_{H_2O} = 0.073$. However, the enzyme-catalyzed conversions of the allomorphs to shorter chains and to α -D-glucose occur after an allomorph has essentially been fully wetted, in which case the allomorph is best described either as (cr, wet) or (am, wet). Unfortunately, we do not have values of the massic Gibbs energies of hydration $\Delta_{hyd} G_w^*$ which are needed to adjust the standard massic Gibbs energies of formation $\Delta_r G_w^\circ$ given in table 24 to the (cr, wet) or (am, wet) states. Also, when these allomorphs are wet, an enzyme (*e.g.* a cellulase), which requires an aqueous environment, can proceed to break down the inter-chain linkages and eventually the glycosidic linkages. Indeed, there may be differences in the rates at which the allomorphs break down. For example, Ciolacu *et al.* [109] demonstrated that cellulose II is more effectively hydrolyzed by several cellulase enzymes than either cellulose I or cellulose III. One must also consider the equilibrium constants or, equivalently the values of $\Delta_r G_w^\circ$, between the polymeric cellulose chains and eventually cellobiose(aq) and α -D-glucose(aq). Indeed, since the final reaction(s) in the conversion of cellulose to α -D-glucose have negative values of $\Delta_r G_m^\circ$ {see the discussion regarding reactions (82), (83), (84), and (85) above} the overall conversion reaction is aided. Additionally, if the α -D-glucose can be removed from the reaction media as it is formed, the entire reaction system will be pulled to the right and to completion by means of Le Chatelier's principle.

We believe that a significant improvement in the accuracy of the thermodynamic properties of the cellulose allomorphs requires the preparation of highly pure samples, *i.e.*, samples that have both high and well-known *CI* values, low amounts of chemical impurities, and a consistent morphology. The availability of high purity samples would also aid in structural investigations of the celluloses as well as other property

measurements. Additionally, due to the paucity and age of the data in the literature, there is a need for modern investigations that will lead to accurate values of $\Delta_{\text{hyd}}H_{\text{w}}^{\circ*}$ and $\Delta_{\text{hyd}}G_{\text{w}}^{\circ*}$ for the pure cellulose allomorphs and to an improved understanding of the nature of water in the celluloses. While values of $\Delta_{\text{hyd}}H_{\text{w}}^{\circ*}$ are best done calorimetrically, the determination of values of $\Delta_{\text{hyd}}G_{\text{w}}^{\circ*}$ require careful vapor pressure measurements together with accurate measurements of the mass fraction of water in the celluloses.

Acknowledgments

We thank Professor Julie Boerio-Goates for providing her fit for the heat capacity of hexagonal ice, Drs. Bruce Coxon and Katrice Lippa for their consultations on the NMR experiments, Drs. Gregg Beckham and Mike Crowley for their helpful discussions and comments on the manuscript, and Drs. Vytas Reipa and Alfons Weber for their help with the foreign language publications. Thanks are also due to Fundação para a Ciência e Tecnologia (FCT), Lisbon, Portugal and to FEDER for financial support given to Centro de Investigação em Química da Universidade do Porto (PEst-C/QUI/UI0081/2013). A.F.L.O.M.S and V.L.S.F. thank FCT and The European Social Fund (ESF) under the Community Support Framework (CSF) for the award of the post-doctoral grants SFRH/BPD/41601/2007 and SFRH/BPD/78552/2011, respectively. This work was supported, in part, by the U.S. Department of Energy under contract no. DE-AC36-08GO28308 and sub-contract no. AEV-2-22205-01 with the National Renewable Energy Laboratory. Funding for the aforementioned contracts was provided by the DOE Office of Energy Efficiency and Renewable Energy, Bioenergy Technologies Office.

Editor's note: Given the length of this manuscript, a list of symbols *etc.* is included below to assist readers. Normally a list of symbols is not included in JCT papers.

Glossary and conventions

<u>Symbol</u>	<u>Name</u>	<u>SI unit</u>
(am)	denotes an amorphous substance	
$A_0, \dots, A_5$	parameters used to fit heat capacities	$\text{J}\cdot\text{K}^{-1}\cdot\text{g}^{-1}, \dots, \text{J}\cdot\text{K}^{-6}\cdot\text{g}^{-1}$
A_r	relative atomic mass	1
B_3, B_5, B_{gap}	parameters used to fit heat capacities	$\text{J}\cdot\text{K}^{-4}\cdot\text{g}^{-1}, \text{J}\cdot\text{K}^{-6}\cdot\text{g}^{-1}, \text{J}\cdot\text{K}^{-5/2}\cdot\text{g}^{-1}$
C_p	heat capacity at constant pressure	$\text{J}\cdot\text{K}^{-1}$
c	concentration	$\text{mol}\cdot\text{dm}^{-3}$
(cad)	denotes a cadoxen solution	
cell	denotes cellulose	
CI	crystallinity index	1
(cr)	denotes a crystalline substance	
DP_w	weight average degree of polymerization	1
ε_i	energy equivalent	$\text{J}\cdot\text{K}^{-1}$
G	Gibbs energy	$\text{J}\cdot\text{mol}^{-1}$
(g)	denotes a gaseous substance	
H	enthalpy	J
(l)	denotes a liquid substance	
m	mass	kg
M_r	relative molecular mass (molar mass)	1
M_w	weight average molar mass	$\text{kg}\cdot\text{mol}^{-1}$
N	number of entities	1
p	pressure	Pa

R	gas constant	$\text{J}\cdot\text{K}^{-1}\cdot\text{mol}^{-1}$
(s)	denotes a solid substance	
S	entropy	$\text{J}\cdot\text{K}^{-1}$
Glossary and conventions (continued)		
t	Celsius temperature	$^{\circ}\text{C}$
T	thermodynamic temperature	K
u	average number of $\text{C}_6\text{H}_{10}\text{O}_5$ units in a cellulose sample	1
$u(x)$	standard uncertainty of a quantity x	
$u_r(x)$	relative standard uncertainty of a quantity x , $u_r(x) = u(x)/ x $	
U	internal energy	J
$U(x)$	expanded uncertainty in a quantity x	
ν	average number of waters of hydration in a cellulose sample	1
w	mass fraction	1
wet	denotes a completely hydrated sample	
$\alpha_1, \alpha_2, \alpha_3$	ratio of molar mass	1
β_1, β_2	ratio of a relative molecular mass to a relative atomic mass	1
γ	mass concentration	$\text{g}\cdot\text{dm}^{-3}$
γ	parameter used to fit heat capacities	$\text{J}\cdot\text{K}^{-2}\cdot\text{g}^{-1}$
δ	parameter used to fit heat capacities	K
Δ	denotes a change	
η	empirical constant { see eq. (24) }	$\text{J}\cdot(\text{g dry}$
Φ	$\Phi = \Delta_0^T S - \Delta_0^T H/T$	$\text{J}\cdot\text{K}^{-1}\text{g}^{-1}$

Subscripts

c	denotes a combustion reaction
cell	denotes cellulose

corr	denotes a corrected value
cr	denotes a crystalline form

Glossary and conventions (continued)

D	denotes a Debye heat capacity
E	denotes an Einstein heat capacity
f	denotes a formation reaction
hyd	denotes hydration { see eq. (5) }
H ₂ O	denotes water
int	denotes intrinsic { see eq. (4) }
m	denotes a molar quantity
r	denotes a reaction
ref	denotes a reference value
sol	denotes a solution reaction
u	denotes a property value based on a monomer
w	denotes a standard massic quantity

Superscripts

°	denotes a standard quantity
*	denotes a pure substance or a reaction involving pure substances

Conventions

The cellulose I, II, and III samples used in this study and in the literature are mixtures of their respective forms with cellulose(am) and are designated as solids, *i.e.* by using an “(s)”. Pure (*i.e.*, $CI = 100$) cellulose I, II, and III are denoted, respectively, as cellulose I(cr), cellulose II(cr), and cellulose III(cr). Pure amorphous cellulose is denoted as cellulose(am). Samples that contain water are denoted by the addition of “ w_{H_2O} ”, *e.g.*, cellulose(am)· w_{H_2O} . While a given cellulose I sample, as an example, could be designated precisely as {cellulose I(cr) + cellulose(am)}, the more compact notation “cellulose I sample” will be used. Clearly, the mass fractions of the two components in a given sample should be specified if known. A superscript “*” is used to denote that a quantity pertains to a pure allomorph ($CI = 100$) or a reaction

Glossary and conventions (continued)

involving pure allomorphs and not a mixture of allomorphs. However, if it is clear that one is dealing with a pure allomorph, a “*” is not placed next to the symbol for a thermodynamic property. The standard state of a solid (or liquid) is the solid (or liquid) at the pressure $p^\circ = 0.1 \text{ MPa}$. Its activity is set to be unity.

TABLE 1. The provenance and estimated mass fraction purities w of the materials used in this study

Substance	Mass fraction	Source
Amorphous cellulose (24 h)	>0.99	^a
Amorphous cellulose (30 h)	>0.99	^a
Amorphous cellulose (36 h)	>0.99	^a
Cadoxen ^b	>0.98 ^c	^a
Cellulose I β ^d	>0.995 ^e	Sigma-Aldrich
Cellulose II (25 °C)	>0.99 ^e	^a
Cellulose II (70 °C)	>0.99 ^e	^a
Cellulose II (145 °C)	>0.99 ^e	^a
Cellulose III (-33 °C)	>0.99 ^e	^a
Cellulose III (25 °C)	>0.99 ^e	^a
Cellulose III (130 °C)	>0.99 ^e	^a
Copper	>0.99999 ^f	Alfa Aesar
Water	^g	NIST

^aPrepared for this study (see section 2.1).

^bCadoxen has the empirical formula $C_6H_{24}CdN_6 \cdot 2H_2O$. Its Chemical Abstracts Service (CAS) registry number is 14874-24-9.

^dThe CAS registry number of cellulose is 9004-34-6. There do not appear to be separate registry numbers for the several cellulose allomorphs.

^eThis purity is estimated and is based, in part, on the information on purity provided by the supplier of the cellulose I β sample. This sample also contained a substantial amount of amorphous cellulose (see table 2).

^fBased on information provided by the supplier.

^gThe mass fraction of organic substances in the NIST supplied distilled water was less than 2×10^{-9} . The conductivity of this water was $\approx 12.6 \text{ M}\Omega$.

TABLE 2. Values of the crystallinity indexes CI for the cellulose samples used in this study^a

Cellulose sample	CI
Amorphous cellulose (24 h)	0
Amorphous cellulose (30 h)	0
Amorphous cellulose (36 h)	0
Cellulose I β	62
Cellulose II (25 °C)	40
Cellulose II (70 °C)	49.2 ± 1.3
Cellulose II (145 °C)	57
Cellulose III (-33 °C)	32
Cellulose III (25 °C)	49
Cellulose III (130 °C)	59.3 ± 1.0

^aThe uncertainties given above for the cellulose II (70 °C) and cellulose III (130 °C) samples are equal to two estimated standard deviations of the mean based on three measurements made on each of these sample. The expanded uncertainties at approximately 95 per cent confidence limits in the values of CI {type B evaluation [48] of $u_r(CI)$ } are equal to $0.06 \cdot CI$.

TABLE 3. Values of the weight average degree of polymerization DP_w of the various forms of cellulose as measured by using gel permeation chromatography^{a,b}

Cellulose sample	$10^{-2} DP_w$
Amorphous cellulose (24 h)	1.9 ± 0.2
Amorphous cellulose (30 h)	1.8 ± 0.3
Amorphous cellulose (36 h)	1.8 ± 0.2
Cellulose I β	4.3 ± 0.5
Cellulose II (25 °C)	7.4 ± 1.0
Cellulose II (70 °C)	4.7 ± 0.5
Cellulose II (145 °C)	0.9 ± 0.2
Cellulose III (-33 °C)	2.8 ± 0.3
Cellulose III (25 °C)	2.9 ± 0.4
Cellulose III (130 °C)	2.8 ± 0.6

^aThe uncertainties given above are expanded uncertainties at approximately 95 per cent confidence limits which have been estimated by combining in quadrature the estimated standard deviations of the mean for each respective measurement result with an estimate of possible systematic error of $0.05 \cdot DP_w$. The coverage factor $k = 2$ for all of the samples except for the cellulose III (130 °C) sample, the value of which is based on a single measurement, an estimated statistical uncertainty of $0.1 DP_w$, and a coverage factor $k = 3$.

^bAn approximate value of the weight average molar mass M_w can be obtained by multiplying DP_w by 162.141, the relative molecular mass (molar mass) of an anhydro glucose unit.

TABLE 4. The mass fraction of water $w_{\text{H}_2\text{O}}$ in the cellulose samples as measured by using Karl Fischer analysis^a

Cellulose sample	Mass fraction H ₂ O
Amorphous cellulose (24 h)	0.0765 ± 0.0029
Amorphous cellulose (30 h)	0.0756 ± 0.0027
Amorphous cellulose (36 h)	0.0773 ± 0.0007
Cellulose I β	0.0485 ± 0.0007
Cellulose II (25 °C)	0.0900 ± 0.0026
Cellulose II (70 °C)	0.0806 ± 0.0030
Cellulose II (145 °C)	0.0710 ± 0.0024
Cellulose III (-33 °C)	0.0811 ± 0.0016
Cellulose III (25 °C)	0.0873 ± 0.0014
Cellulose III (130 °C)	0.0931 ± 0.0007

^aThe uncertainties in w given above are expanded uncertainties with approximately 95 per cent confidence limits. These uncertainties include the statistical uncertainties in the mass fraction of water in the calibrant (octanol + water) solution, in the calibrations [25], and in the measurements on the cellulose samples. Three to four measurements were performed on each sample.

TABLE 5. Mass fractions w and mass concentrations γ of the cellulose samples in cadoxen used in the NMR experiments.

Cellulose sample	Mass fraction	Mass concentration $/(\text{g}\cdot\text{cm}^{-3})^a$
Amorphous (24 h)	0.009516	0.01021
Amorphous (30 h)	0.009530	0.01023
Amorphous (36 h)	0.009433	0.01012
Amorphous (36 h)	0.004676	0.005018
I β	0.009400	0.01009
II (25 °C)	0.004724	0.005070
II (70 °C)	0.004741	0.005088
II (145 °C)	0.004639	0.004979
III (-33 °C)	0.009330	0.01001
III (-33 °C)	0.009457	0.01015
III (-33 °C)	0.009455	0.01015
III (25 °C)	0.009515	0.01021
III (130 °C)	0.009412	0.01010

^aThe mass concentrations of the cellulose samples in cadoxen were calculated from the mass fractions by using a measured density of $(1.0732 \pm 0.0004) \text{ g}\cdot\text{cm}^{-3}$ for cadoxen. The estimated relative standard uncertainties (type B evaluation) are $u_r(w) = u_r(\gamma) = 0.001$.

TABLE 6. Results of combustion experiments on cellulose samples at the temperature $T = 298.15$ K and the standard pressure $p^\circ = 0.1$ MPa^a

^aAll uncertainties in this table are expanded uncertainties with approximately 95 per cent confidence limits; $m(\text{CO}_2, \text{total})$ is the mass of CO_2 recovered in each combustion; $m(\text{cell})$ is the mass of compound burned in each experiment; $m(\text{cell}_{\text{corr}})$ is the mass of compound corrected for the mass fraction of CO_2 formed; $m'(\text{fuse})$ is the mass of the fuse (cotton) used in each experiment; ΔT_{ad} is the corrected temperature rise; ε_f is the energy equivalent of the contents in the final state; $\Delta U(\text{IBP})$ is the energy change for the isothermal combustion reaction under actual bomb conditions and includes $\Delta U(\text{ignition})$; $\Delta U(\text{fuse})$ is the energy of combustion of the fuse (cotton); $\Delta U(\text{HNO}_3)$ is the energy correction for the nitric acid formation; $\Delta U(\text{carb})$ is the energy correction for the carbon soot formation; $\Delta U(\text{ign})$ is the electric energy for the

TABLE 6 (continued)

ignition; ΔU_{Σ} is the standard state correction; $-\Delta_c U_w^{\circ}(\text{CO}_2)$ is the standard massic energy of combustion based on the mass of CO_2 formed in each experiment; and $w(\text{CO}_2)$ is the mass fraction of CO_2 formed. The estimated standard uncertainties in the temperature T and pressure p are $u(T) = 0.001$ K and $u(p) = 100$ Pa.

$^b \Delta m(\text{H}_2\text{O})$ is the deviation of mass of water added to the calorimeter from 3119.6 g;

$^{b'} \Delta m(\text{H}_2\text{O})$ is the deviation of mass of water added to the calorimeter from 2900.0 g.

$^c \Delta U(\text{IBP}) = -\{ \varepsilon(\text{calor}) + C_{p,w}(\text{H}_2\text{O}, \text{l}) \cdot \Delta m(\text{H}_2\text{O}) + \varepsilon_f \} \Delta T_{\text{ad}} + \Delta U(\text{ign})$, where $\varepsilon(\text{calor})$ is the energy equivalent of the calorimeter and $C_{p,w}$ is the standard massic heat capacity of $\text{H}_2\text{O}(\text{l})$ at $T = 298.15$ K.

TABLE 7. Values of $\Delta_c H_w^\circ$, the standard massic enthalpy of combustion, w_{H_2O} , the total mass fraction of water in the sample, and $\Delta_c H_w^\circ(w_{ref} = 0.073)$, the standard massic enthalpy of combustion at the mass fraction of water $w_{ref} = 0.073$. The temperature $T = 298.15$ K and $p^\circ = 0.1$ MPa.

TABLE 7 (continued)

^aThe standard massic enthalpy of combustion $\Delta_c H_w^\circ$ was calculated as follows (also see table 6):

$$\Delta_c H_w^\circ = \Delta_c U_w^\circ(\text{CO}_2) \cdot m(\text{cell}_{\text{corr}}) / m(\text{cell}).$$

^bThe mass fraction of water $w_{\text{H}_2\text{O}}$ is based on the mass of $\text{CO}_2(\text{g})$ produced {see eq. (10)}.

^cThe quantity $\Delta_c H_w^\circ(w_{\text{ref}} = 0.073)$ is the standard massic enthalpy of combustion at the mass fraction of water $w_{\text{ref}} = 0.073$. This quantity was calculated by using eqs. (23) and (24).

^dAll uncertainties correspond to expanded uncertainties with approximately 95 per cent confidence limits.

^a $\Delta_c H_w^\circ(w_{\text{ref}} = 0.073)$ is the standard massic enthalpy of combustion of the specified sample at the mass fraction of water $w_{\text{ref}} = 0.073$ (see table 7) and $\Delta_c H_w^{\circ*}$ is the standard massic enthalpy of combustion of the specified form of pure cellulose at the mass fraction of water $w_{\text{ref}} = 0.073$. $\Delta_c H_w^{\circ*}$ is calculated using eq. (25) and the values of w_{cr} which are based on the measured values of the crystallinity indexes.

All uncertainties correspond to expanded uncertainties with approximately 95 per cent confidence limits.

^bThe average of the values of $\Delta_c H_w^{\circ*}(w_{\text{ref}} = 0.073)$ for the amorphous cellulose samples is $-(16062 \pm 14) \text{ J}\cdot\text{g}^{-1}$.

This is taken to be the value for $\Delta_c H_w^{\circ*}(w_{\text{ref}} = 0.073)$ for cellulose(am).

^cBy taking weighted averages the following values are obtained: $\Delta_c H_w^{\circ*} = -(15919 \pm 84) \text{ J}\cdot\text{g}^{-1}$ for cellulose II(cr) and $\Delta_c H_w^{\circ*} = -(16085 \pm 56) \text{ J}\cdot\text{g}^{-1}$ for cellulose III(cr).

TABLE 9. Values of $\Delta_r H_w^{\circ*}$, the standard massic enthalpy changes for reactions (26) to (31) obtained from combustion calorimetry. All reactions pertain to $T = 298.15$ K, $p^\circ = 0.1$ MPa, and $w_{H_2O} = 0.073$.

H ₂ O(l)	3	$-(24.00 \pm 0.21)$		

^aThe quantities are defined as follows: $\Delta_{\text{sol}}H_{\text{w}}^{\circ}$ is the measured standard massic enthalpy of solution of the specified sample; N is the number of measurements; $\Delta_{\text{sol}}H_{\text{w}}^{\circ}(w_{\text{ref}} = 0.073)$ is the standard massic enthalpy of solution of the specified sample at the mass fraction of water $w_{\text{ref}} = 0.073$ and is calculated from $\Delta_{\text{sol}}H_{\text{w}}^{\circ}$ (column 3) by using eqs. (56) and (24); and $\Delta_{\text{sol}}H_{\text{w}}^{\circ*}$ is the standard massic enthalpy of solution of the specified cellulose allomorph at the mass fraction of water $w_{\text{ref}} = 0.073$ and is calculated by using eq. (57). The estimated standard uncertainties in the temperature T and pressure p are $u(T) = 0.05$ K and $u(p) = 0.004$ MPa. The uncertainties given in column 3 and 4 correspond to expanded uncertainties with approximately 95 per cent confidence limits. The uncertainties given in column 5 were obtained by combining in quadrature the uncertainties in the respective values of $\Delta_{\text{sol}}H_{\text{w}}^{\circ}(w_{\text{ref}} = 0.073)$ with the uncertainty in the average value of $\Delta_{\text{sol}}H_{\text{w}}^{\circ*}(w_{\text{ref}} = 0.073)$ for the amorphous cellulose samples and thus also correspond to expanded uncertainties with approximately 95 per cent confidence limits.

TABLE 10 (continued)

^bThe final mass concentrations of the cellulose allomorphs in the 100.0 cm³ of cadoxen in the calorimeter were $\approx 0.20 \text{ g}\cdot\text{dm}^{-3}$. The final mass concentration of the water in the 100.0 cm³ of cadoxen in the calorimeter was $\approx 0.91 \text{ g}\cdot\text{dm}^{-3}$.

^cIt was not possible to perform measurements with the cellulose II (25 °C) sample due to the formation of a large clump (moist, compacted mass) of the sample which did not dissolve in the cadoxen. This clumping was observed in two independent experiments. Interestingly, this sample of cellulose II dissolved in cadoxen with gentle shaking in a small bottle placed in a constant temperature bath at 25.0 °C. Clearly, the stirring action in the calorimeter is different than that which is obtained using a shaking device. This problem was not observed when using the other cellulose samples.

^dThe average of the values of $\Delta_{\text{sol}}H_{\text{w}}^{\circ}(w_{\text{ref}} = 0.073)$ for the amorphous cellulose samples is $-(156.1 \pm 2.3) \text{ J}\cdot\text{g}^{-1}$. This is taken to be the value for $\Delta_{\text{sol}}H_{\text{w}}^{\circ*}(w_{\text{ref}} = 0.073)$ for cellulose(am).

TABLE 11. ^aThe estimated standard uncertainties in the temperature T and pressure p are $u(T) = 0.001$ K and $u(p) = 0.10$ mPa. The expanded uncertainties at approximately 95 per cent confidence limits in the values of $C_{p,w}^{\circ}$ are $U(C_{p,w}^{\circ}) = 0.02 \cdot C_{p,w}^{\circ}$ ($2 < T/K < 20$) and $U(C_{p,w}^{\circ}) = 0.01 \cdot C_{p,w}^{\circ}$ ($10 < T/K < 302$).

TABLE 14. The fitting parameters {see eqs. (73) and (74)} of the heat-capacity data for the cellulose samples at $p^\circ = 1.2$ mPa covering the range $T = (1.9 \text{ to } 305)$ K. The fits are divided into three overlapping ranges: $T < 13$ K (low T), $10 \text{ K} < T < 37$ K (mid T), and $T > 33$ K (high T). The root-mean-square (RMS) deviations of the fits over the specified temperature ranges are also given.

TABLE 15. Standard thermodynamic functions for the cellulose samples as a function of temperature at $p^\circ = 0.1$

MPa: $C_{p,w}^\circ$ is the standard massic heat capacity; $\Delta_0^T S_w^\circ$ is the standard massic entropy difference $\{S_w^\circ(T) - S_w^\circ(T=0)\}$, $\Delta_0^T H_w^\circ$ is the standard massic enthalpy difference $\{H_w^\circ(T) - H_w^\circ(T=0)\}$, and the function $\Phi_w^\circ = \Delta_0^T S_w^\circ - \Delta_0^T H_w^\circ/T$.

Uncertainties are discussed in section 3.8.

^aThe standard uncertainties in the temperatures T are $u(T) = 0.001$ K.. The expanded uncertainties in the property values $C_{p,w}^\circ$, $\Delta_0^T S_w^\circ$, and $\Delta_0^T H_w^\circ$ at approximately 95 per cent confidence limits are: $U(C_{p,w}^\circ) = 0.02 \cdot C_{p,w}^\circ$ ($2 < T/K < 20$) and $U(C_{p,w}^\circ) = 0.01 \cdot C_{p,w}^\circ$ ($10 < T/K < 302$); $U(\Delta_0^T S_w^\circ) = 0.02 \cdot \Delta_0^T S_w^\circ$ ($2 < T/K < 20$) and $U(\Delta_0^T S_w^\circ) = 0.01 \cdot \Delta_0^T S_w^\circ$ ($10 < T/K < 302$); and $U(\Delta_0^T H_w^\circ) = 0.02 \cdot \Delta_0^T H_w^\circ$ ($2 < T/K < 20$) and $U(\Delta_0^T H_w^\circ) = 0.01 \cdot \Delta_0^T H_w^\circ$ ($10 < T/K < 302$).

The expanded uncertainties in $U(\Phi_w^\circ)$ are temperature dependent and can be calculated by combining in quadrature the values of $U(\Delta_0^T S_w^\circ)$ and $U(\Delta_0^T H_w^\circ)/T$.

TABLE 16. Standard thermodynamic functions for the cellulose samples and for the pure allomorphs at $T = 298.15$ K and $p^\circ = 0.1$ MPa: $C_{p,w}^\circ$ is the standard massic heat capacity; $\Delta_0^T S_w^\circ$ is the standard massic entropy difference $\{S_w^\circ(T) - S_w^\circ(T = 0)\}$, $\Delta_0^T H_w^\circ$ is the standard massic enthalpy difference $\{H_w^\circ(T) - H_w^\circ(T = 0)\}$, and the function $\Phi_w^\circ = \Delta_0^T S_w^\circ - \Delta_0^T H_w^\circ/T$. All values except the “Measured” ones are corrected to a water mass fraction $w_{\text{ref}} = 0.073$ using eq. (67). The basis for the expanded uncertainties (approximately 95 per cent confidence limits) in these property values is discussed in section 3.8.

TABLE 17. Calculated property values for the conversion reactions of the cellulose allomorphs at $T = 298.15$ K and $p^\circ = 0.1$ MPa. Here, ΔH_w° is the change in the standard massic enthalpy, ΔG_w° is the change in the standard massic Gibbs energy, ΔS_w° is the change in the standard massic entropy, and $\Delta C_{p,w}^\circ$ is the change in the standard massic heat capacity. All substances in these reactions are a mass fraction of water $w_{\text{H}_2\text{O}} = 0.073$. The uncertainties are expanded uncertainties **at approximately 95 per cent confidence limits**.

Reaction	$\Delta_r H_w^\circ / (\text{J} \cdot \text{g}^{-1})$	$\Delta_r G_w^\circ / (\text{J} \cdot \text{g}^{-1})$	$\Delta_r S_w^\circ / (\text{J} \cdot \text{K}^{-1} \cdot \text{g}^{-1})^a$	$\Delta_r C_{p,w}^\circ / (\text{J} \cdot \text{K}^{-1} \cdot \text{g}^{-1})$

^aThe values of $\Delta_r S_w^\circ$ and $\Delta_r G_w^\circ$ are based on the assumption that the values of S_w° for all of the allomorphs approach the same value as $T \rightarrow 0$. See section 3.9.

TABLE 18. Summary of results from the literature for the standard massic enthalpy change $\Delta_r H_w^{\circ*}$ for reactions (26), (27), (28), and (29). The temperature $T = 298.15$ K except for the studies of Calvet [62] and Calvet and Hermans^a [63] where $T = 290.15$ K. The pressure $p^\circ \approx 0.1$ MPa. The uncertainties are either those reported by the authors or calculated from their reported property values, in which case the uncertainties are based on two estimated standard deviations of the mean.

^aCalvet and Hermans [63] dissolved samples of rayon and cotton linters in cupriethylenediamine solution at $T = 290.15$ K. The CI values of the samples they [63] used were based on X-ray diffraction data. Note that the reaction is clearly exothermic even though Calvet and Hermans [63] give a positive sign for $\Delta_r H_w^{\circ*}$. A relative molecular mass $M_r = 162.141$ was used to convert their [63] reported value of $\Delta_r H_m^{\circ*}$ to a standard massic basis. More importantly, in the treatment of their results, Calvet and Hermans [63] made no distinction of the fact that rayon is cellulose II and that cotton linters are cellulose I. Thus, the value of $\Delta_r H_w^{\circ*} = -106 \text{ J} \cdot \text{g}^{-1}$ obtained from the study of Calvet and Hermans is, in fact, the average of the values of $\Delta_r H_w^{\circ*}$ for reactions (26) and (27). Calvet and Hermans also measured values of $\Delta_{\text{hyd}} H_w^{\circ}(0 \rightarrow \text{wet})$ for the rayon and cotton linter samples. However, since they did not measure a value $\Delta_{\text{hyd}} H_w^{\circ}(0 \rightarrow \text{wet})$ for cellulose(am), it is not possible to calculate values of $\Delta_{\text{hyd}} H_w^{\circ*}(0 \rightarrow \text{wet})$ for pure cellulose I(cr) or pure cellulose II(cr). Nevertheless, the values of $\Delta_{\text{hyd}} H_w^{\circ}(0 \rightarrow \text{wet})$ measured by Calvet and Hermans [63] are in accord with those obtained by Rees [15].

^bNelson [14] used cupriethylenediamine to dissolve cellulose samples and a thermochemical cycle to obtain values

TABLE 18 (continued)

of $\Delta_{\text{sol}}H_w^{\circ*}$ ($w_{\text{H}_2\text{O}} = 0$). The values of $\Delta_rH_w^{\circ*}$ given here are based on the summary of results given on page 79 of Nelson's thesis. The uncertainty is an estimate based on the value assumed for the crystallinity index for the cellulose sample (N7) having the lowest crystallinity. The temperature is presumably 298.15 K.

^cDale and Tsao [64] dissolved samples of cellulose I, cellulose II, and amorphous cellulose in cadoxen and in ferric sodium tartrate. All of the samples were dry. The result given here is based on experiments that used cadoxen. The uncertainties are based on the high and low values given in their table V. The reaction temperature was 298.15 K [Bruce Dale, personal communication].

^dThis result, obtained by Dale and Tsao [64], is based on experiments that used ferric sodium tartrate.

^eCalculated from the values of $\Delta_rH_w^{\circ*}$ that pertain to $w_{\text{H}_2\text{O}} = 0.073$. The uncertainties are expanded uncertainties and include estimates for possible errors in the values of $\Delta_{\text{hyd}}H_w^{\circ*}$.

^fCalvet [62] gives $\Delta_rH_w^{\circ*} = -4 \text{ cal}\cdot\text{g}^{-1}$ at $T = 290.15 \text{ K}$ but states that the reaction is endothermic for the mercerization reaction of wet cellulose. By using values of $\Delta_{\text{hyd}}H_w^{\circ*}(0 \rightarrow \text{wet})$ for cellulose I(cr) and cellulose II(cr) calculated from Nelson's study [14] (see section 3.10.1), we calculated $\Delta_rH_w^{\circ*} = 12 \text{ J}\cdot\text{g}^{-1}$ for reaction (29) that pertains to $w_{\text{H}_2\text{O}} = 0$.

^gLauer [65] reports $\Delta_rH^\circ = "1108 \text{ cal/C}_6\text{H}_{10}\text{O}_5"$ for the mercerization reaction of wet cellulose. This corresponds to $\Delta_rH_w^\circ \approx 29 \text{ J}\cdot\text{g}^{-1}$ for reaction (29). By using values of $\Delta_{\text{hyd}}H_w^{\circ*}(0 \rightarrow \text{wet})$ for cellulose I(cr) and cellulose II(cr) calculated from Nelson's study [14] (see section 3.10.1), we calculate $\Delta_rH_w^{\circ*} \approx 24 \text{ J}\cdot\text{g}^{-1}$ for reaction (29) that pertains to $w_{\text{H}_2\text{O}} = 0$. The sign of the enthalpy change is uncertain.

^hRanby [49], in his study and review, calculated $\Delta_rH_w^{\circ*} \approx -8 \text{ J}\cdot\text{g}^{-1}$ for the mercerization reaction of wet cellulose from the enthalpy of solution measurements of Morrison *et al.* [66, 67] in which NaOH was used. Ranby [49] also summarized the earlier studies [68-74] on the mercerization reaction. By using values of $\Delta_{\text{hyd}}H_w^{\circ*}(0 \rightarrow \text{wet})$ for cellulose I(cr) and cellulose II(cr) calculated from Nelson's study [14] (see section 3.10.1), we calculate $\Delta_rH_w^{\circ*} = -13 \text{ J}\cdot\text{g}^{-1}$ for reaction (29) that pertains to $w_{\text{H}_2\text{O}} = 0$.

ⁱCalculated from the results of Nelson [14] by using her results for reactions (26) and (27) given in this table.

^jCalculated from the results of Dale and Tsao [64] by using their results for reactions (26) and (27) given in this table.

TABLE 18 (continued)

^kIoelovich [75] measured values of $\Delta_{\text{sol}}H_{\text{w}}^{\circ}$ for samples of cellulose I and cellulose II into cadoxen. He [75] used two samples for both cellulose I and cellulose II, each of which had different CI values. We extrapolated the respective values of $\Delta_{\text{sol}}H_{\text{w}}^{\circ}$ to $CI = 100$ and then subtracted the resultant values of $\Delta_{\text{sol}}H_{\text{w}}^{\circ*}$ for the two pure allomorphs to obtain $\Delta_{\text{r}}H_{\text{w}}^{\circ*} = -55 \text{ J}\cdot\text{g}^{-1}$ for reaction (29). This result pertains to $w_{\text{h}_2\text{O}} = 0$.

TABLE 19. Summary of results from the literature for the standard massic enthalpies of combustion $\Delta_c H_w^\circ$ of samples of cellulose in oxygen {reaction (9)}. The mass fractions of water w_{H_2O} and crystallinity indexes CI , if reported, are given in columns 3 and 4, respectively. The values of $\Delta_c H_w^\circ$ given in column 5 refer to $T = 298.15$ K and $p^\circ = 0.1$ MPa. The uncertainties are either those reported by the authors or calculated from their results, in which case the uncertainties are based on two estimated standard deviations of the mean.^{a, b, c}

^aFor the combustion of cellulose in oxygen {reaction (9)}, $\Delta_c H_w^\circ = \Delta_c U_w^\circ$. The uncertainties are those given by the investigators.

^bCalories were converted to joules by using the relationship 1 cal_{th} = 4.184 J.

^cIn two cases [80, 84] where the results were very precise, the values of $\Delta_c H_w^\circ$ were adjusted from the temperature at which the combustion took place to $T = 298.15$ K. This adjustment required a value of $\Delta_c C_{p,w}^\circ$ for reaction (9). This value was calculated by using the standard molar heat capacities tabulated by Wagman *et al.* [107] for O₂(g), CO₂(g), and H₂O(l). Thus, for cellulose I having $w_{H_2O} = 0$ and $CI = 0.76$, $C_{p,w}^\circ = 1.23 \text{ J} \cdot \text{K}^{-1} \cdot \text{g}^{-1}$ [89] and $\Delta_c C_{p,w}^\circ = 1.38 \text{ J} \cdot \text{K}^{-1} \cdot \text{g}^{-1}$.

^dBinder [77] reports $\Delta_c H_w^\circ = 4189 \text{ cal} \cdot \text{g}^{-1}$. Few details are given. This is an approximate value.

^eKarrer and Fioroni [78] report $\Delta_c H_w^\circ = 4185 \text{ cal} \cdot \text{g}^{-1}$. This is an approximate value.

TABLE 19 (continued)

^fHeisenberg's [79] values are approximate.

^gJessup and Prosen [80] made a correction for $\Delta_{\text{hyd}}H_w^\circ$ for both samples studied. We applied small corrections (see note c above) to adjust their measured values from $T = 303.15$ K to $T = 298.15$ K. The ratios of CO_2 formed to CO_2 calculated are 0.99576 and 0.99590 for the two samples studied. The uncertainties given to the values of $\Delta_c H_w^\circ$ in column 5 were calculated from the results given in their [80] table 3.

^hNelson [14] used both acid hydrolysis to measure the CI values for all of the cellulose samples. These CI values are given in the above table. CI values were also measured for the two cellulose I samples by using XRD. These values are: $CI = 80$ for the "cotton yarn kiln-dried" sample and $CI = 70$ for the "hydrocellulose prepared" sample. We have rounded Nelson's CI values.

ⁱTang and Neill [81] gave few details in their study. This value is approximate.

^jSusott *et al.* [82]. Susott *et al.* [82] reported $\Delta_c H_w^\circ = -4143 \text{ cal} \cdot \text{g}^{-1} = -17334 \text{ J} \cdot \text{g}^{-1}$ on a dry weight basis, *i.e.* $\Delta_c H_w^\circ(\text{dry}) = \Delta_c H_w^\circ(\text{wet})/(1 - w_{\text{H}_2\text{O}})$. The value of $\Delta_c H_w^\circ$ given in column 5 refers to the wet or "as burned" basis.

^kMurphey and Master [83] gave few details in their study. This value is approximate.

^lColbert *et al.* [84] dried the cellulose sample and added a small amount of water prior to combustion. The reason for this, they [84] noted, was that extremely dry cellulose does not produce a complete burn. They [84] made a correction to the measured enthalpy change for water using Rees' data [15]. The combustion produced a negligible amount of ash. The mass fraction purity by CO_2 analysis was 0.9981 ± 0.0010 . Colbert *et al.* [84] report $\Delta_c U_w^\circ = -(17340.76 \pm 10.64) \text{ J} \cdot \text{g}^{-1}$ at $T = 301.15$ K. We apply a small correction (see note c above) to adjust their measured value to $T = 298.15$ K.

^mIoelovich *et al.* [85] report values of $\Delta_c H_w^\circ$ in $\text{kJ} \cdot \text{mol}^{-1}$. These values were converted to a standard massic basis by using a relative molecular mass $M_r = 162.141$.

ⁿChen and Frendi [86] gave few details in their study. This value is approximate.

^oMilosavljevic *et al.* [87] gave few details in their study. This value is approximate.

TABLE 19 (continued)

^pUr'yash *et al.* [88]. The *CI* value for the sample of microcrystalline cellulose was estimated based on comparisons with their measured standard massic enthalpies of combustion having known *CI* values. They [88] also stated that used reformed wood cellulose that was 98% α -cellulose. However, the fact that the cellulose was from wood implies that the sample was cellulose I β .

^qBlokhin *et al.* [89] report the mass fraction impurities of ash and sulfur in their samples. The values of $\Delta_c H_w^\circ$ given here refer to the ash free samples.

TABLE 20. Summary of results from the literature for standard massic enthalpies of combustion $\Delta_c H_w^{\circ*}$ at $T = 298.15$ K, $p^\circ = 0.1$ MPa, and $w_{H_2O} = 0$ for cellulose(am), cellulose I(cr), cellulose II(cr), and cellulose III(cr). The basis for these values is given in section 3.10.3. The uncertainties are either those reported by the authors or calculated from their results, in which case the uncertainties are based on two estimated standard deviations of the mean.

^aFew details are given in this early study by Fleury [90].

^bFew details are given in this early study by Padoa [91].

^cShipley *et al.* [92] used an adiabatic calorimeter for their measurements and tabulate values of $C_{p,w}^{\circ}$ at $T = (213.15, 233.15, 253.15, 273.15, \text{ and } 293.15) \text{ K}$. The value given in column 5 was extrapolated from these values.

^dMikhailov and Fainberg [93] did not report the temperature at which they measured $C_{p,w}^{\circ}$. We assume that $T = 298.15 \text{ K}$.

^eFainberg and Mikhailov [94] measured heat capacities from $T = (333 \text{ to } 473) \text{ K}$. The values of $C_{p,w}^{\circ}$ given in column 5 were extrapolated to $T = 298.15 \text{ K}$ by using the functions given by Fainberg and Mikhailov [94] (see their table 2).

^fMcMillin [95] measured values of $C_{p,w}^{\circ}$ at $T = (333, 373, \text{ and } 413) \text{ K}$ using a DSC. The value of $C_{p,w}^{\circ}$ given in column 5 is extrapolated from these values and pertains to $T = 298.15 \text{ K}$.

^gKozlov *et al.* [13] used samples of cellulose I that were dried at (80, 110, and 150) °C for six hours. Standard massic heat capacities of these samples were measured in an adiabatic calorimeter from $T = (80 \text{ to } 320) \text{ K}$. The results are presented only in graphical form. Very substantial differences in property values are seen in the $C_{p,w}^{\circ}$ values with the three samples dried at different temperatures.

^hKozlov *et al.* [96] measured values of $C_{p,w}^{\circ}$ from $T = (80 \text{ to } 300) \text{ K}$ for four samples of cellulose I from cotton. The samples were either solvent (methanol, ether, and hexane) dried or oven dried at 135 °C. CI values were determined by using XRD. The values of $C_{p,w}^{\circ}$ given in column 5 were obtained by interpolation from the tabulated $C_{p,w}^{\circ}$ values. The values of $\Delta_0^T S_w^{\circ}$ and $\Delta_0^T H_w^{\circ}$ were calculated from the values tabulated by Kozlov *et al.* [96] by using a Hermite polynomial fit to the $C_{p,w}^{\circ}$ values and an empirical extrapolation to $T = 0$ followed by the necessary integrations.

ⁱKarachevtsev and Kozlov [97] measured the heat capacities of 13 cellulose samples that were dried at various temperatures. Water was removed by placing samples under high vacuum for 30 to 40 h until there was no flow in the system. They [97] used an adiabatic calorimeter to measure heat capacities from (80 to

TABLE 21 (continued)

300) K on these 13 samples. They [97] give values of $C_{p,m}^{\circ}$ only in graphical form. However, they [97] reported values of $\Delta_0^T S_m^{\circ}$. Considerable differences were found in the values of $C_{p,w}^{\circ}$ and $\Delta_0^T S_w^{\circ}$ for samples that had been oven dried at various temperatures even though their XRD patterns were the same. Indeed, the values of $\Delta_0^T S_w^{\circ}$ ($T = 300$ K) varied from (0.68 to 1.44) $\text{J}\cdot\text{K}^{-1}\cdot\text{g}^{-1}$. Here, we used a molar mass of $162.141 \text{ g}\cdot\text{mol}^{-1}$ to calculate values of $\Delta_0^T S_w^{\circ}$. In view of the large scatter in their [97] results, no values of $C_{p,w}^{\circ}$ and $\Delta_0^T S_w^{\circ}$ are given in this table.

^jKaimins [98] measured heat capacities from $T = (160 \text{ K to } 350) \text{ K}$. The results are given only in graphical form.

^kHatakema *et al.* [99] measured values of $C_{p,w}^{\circ}$ from $T = (350 \text{ to } 435) \text{ K}$ with a DSC. The CI values were obtained by using XRD. The values of $C_{p,w}^{\circ}$ given in column 5 were obtained by extrapolation to $T = 298.15 \text{ K}$ and the use of the coefficients given in their [99] table 1. Extrapolation of the $C_{p,w}^{\circ}$ values having the highest CI values to $CI = 100$, gives $C_{p,w}^{\circ*} = 1.079 \text{ J}\cdot\text{K}^{-1}\cdot\text{g}^{-1}$ for cellulose I(cr) with $CI = 100$. The same results were published in a conference proceedings [100].

^lMochalov *et al.* [101] measured values of $C_{p,w}^{\circ}$ from $T = (80 \text{ to } 400) \text{ K}$ by using an adiabatic calorimeter. Samples were vacuum dried at $T = 370 \text{ K}$. CI values were determined by using XRD. They [101] tabulated property values ($C_{p,w}^{\circ}$, $\Delta_0^T H^{\circ}$, and $\Delta_0^T S^{\circ}$) from 10 K to 400 K . The property values given in this table were obtained by interpolation of the values reported by Mochalov *et al.* [101].

^mUr'yash *et al.* [88] used an adiabatic calorimeter to measure values of $C_{p,w}^{\circ}$ from $T = (80.05 \text{ to } 329.3) \text{ K}$. The CI value for the sample of microcrystalline cellulose was estimated based on comparisons with their measured standard massic enthalpies of combustion having known CI values. The values of $C_{p,m}^{\circ}$ were converted to a standard massic basis by using the relative molecular mass $M_r = 162.14$ used by Ur'yash *et al.* [88]. Integration of their results [88] gives the values of $\Delta_0^T S_w^{\circ}$ and $\Delta_0^T H_w^{\circ}$ given in columns 6 and 7, respectively. The values of $\Delta_0^T S_w^{\circ}$ and $\Delta_0^T H_w^{\circ}$ were calculated from the values tabulated by Ur'yash *et al.* [88] by using a Hermite polynomial fit to the $C_{p,w}^{\circ}$ values and an empirical extrapolation to $T = 0$ followed by the necessary integrations.

ⁿBlokhin *et al.* [89] used an adiabatic calorimeter to measure values of $C_{p,m}^{\circ}$ from $T = (5 \text{ to } 368) \text{ K}$. They also report the mass fraction impurities of ash and sulfur in their samples. The reported property values ($C_{p,m}^{\circ}$, $\Delta_0^T H_m^{\circ}$, and $\Delta_0^T S_w^{\circ}$) were converted from a molar basis to a standard massic basis by using a relative molecular

TABLE 21 (continued)

mass $M_r = 162.141$. Uryash *et al.* [88] also report thermal anomalies (“relaxation transitions”) in the range $T = (284 \text{ to } 343) \text{ K}$. These anomalies are not seen in our results nor in the results of Blokhin *et al.* [89].

TABLE 22. Summary of results from the literature for the standard massic heat capacities $C_{p,w}^{\circ*}$, the standard massic entropy differences $\Delta_0^T S_w^{\circ*} = \{S_w^{\circ*}(T) - S_w^{\circ*}(T=0)\}$, the standard massic enthalpy differences $\Delta_0^T H_w^{\circ*} = \{H_w^{\circ*}(T) - H_w^{\circ*}(T=0)\}$, and the function $\Phi_w^{\circ*} = (\Delta_0^T S_w^{\circ*} - \Delta_0^T H_w^{\circ*}/T)$ for cellulose(am) and for cellulose I(cr) at $T = 298.15$ and $p^\circ = 0.1$ MPa. The results obtained by Hatakema *et al.* [99], Mochalov *et al.* [101], and Blokhin *et al.* (2011) pertain to a mass fraction of water $w_{H_2O} = 0$. The results of this study were obtained at $w_{H_2O} = 0.073$. Eq. (77) was used to calculate the values from our study that pertain to $w_{H_2O} = 0$. The uncertainties in the values from our study are expanded uncertainties at approximately 95 per cent confidence limits.

TABLE 23. Summary of results from the literature for the changes in the standard massic entropy $\Delta_r S_w^{\circ*}$ and in the standard massic heat capacity $\Delta_r C_{p,w}^{\circ*}$ for the reaction {cellulose(am) = cellulose I(cr)}, reaction (26), at $T = 298.15$ K and $p^\circ = 0.1$ MPa calculated from results in the literature. The results obtained by Hatakema *et al.* [99], Mochalov *et al.* [101], and Blokhin *et al.* [89] pertain to a mass fraction of water $w_{\text{H}_2\text{O}} = 0$. The results of this study were obtained at $w_{\text{H}_2\text{O}} = 0.073$. Eq. (77) was used to calculate the values from our study that pertains to $w_{\text{H}_2\text{O}} = 0$. The values of $\Delta_r S_w^{\circ*}$ are based on the assumption that the values of $S_w^{\circ*}$ for cellulose(am) and cellulose I(cr) approach the same value as $T \rightarrow 0$. The uncertainties in the values from our study are expanded uncertainties at approximately 95 per cent confidence limits.

Table 24. Standard formation properties of cellulose(am), cellulose I(cr), cellulose II(cr), and cellulose III(cr) at $T = 298.15$ K and $p^\circ = 0.1$ MPa. The quantity $\Delta_f H_w^\circ$ is the standard massic enthalpy of formation, $\Delta_f G_w^\circ$ is the standard massic Gibbs energy of formation, S_w° is the standard massic entropy, and $C_{p,w}^\circ$ is the standard massic heat capacity. The corresponding quantities for the monomer unit $C_6H_{10}O_5$ are $\Delta_f H_u^\circ$, $\Delta_f G_u^\circ$, S_u° , and $C_{p,u}^\circ$. For cellulose having a mass fraction of water $w_{H_2O} = 0.073$, the relative molecular mass of the monomer unit is $M_r = 174.909$. For anhydrous cellulose, the relative molecular mass of the monomer unit is $M_r = 162.141$.^{a,b,c}

^aThe values of S_w° , S_u° , $\Delta_f G_w^\circ$, and $\Delta_f G_u^\circ$ are based on the assumption (see section 3.11) that the measured values of $\Delta_f S_w^\circ$ (see table 16) are equal to S_w° .

^bSince it is clear that all substances in this table are the pure allomorphs, a “*” is not placed next to the symbol for a thermodynamic property.

^cThe uncertainties given above are expanded uncertainties at approximately 95 per cent confidence limits. They were calculated by using propagation of error together with the uncertainties given previously (see tables 8, 16, and 17) and the uncertainties in the property values of C(s), H₂(g), O₂(g), H₂O(l), and CO₂(g) given in the CODATA Tables [102]. No component of uncertainty due to the assumption given in footnote “a” is included in the uncertainties.

Table 25. Standard thermodynamic quantities for the conversion reactions $\{(C_6H_{10}O_5)_u \cdot (H_2O)_1 \cdot (H_2O)_v(s) + (u - v - 1) H_2O(l) = u C_6H_{12}O_6(cr)\}$ of the cellulose allomorphs to α -D-glucose(cr) at $T = 298.15$ K and $p^\circ = 0.1$ MPa. The quantity $\Delta_r H_w^\circ$ is the standard massic enthalpy change, $\Delta_r G_w^\circ$ is the standard massic Gibbs energy change, $\Delta_r S_w^\circ$ is the standard massic entropy change, and $\Delta_r C_{p,w}^\circ$ is the standard massic heat capacity change. The corresponding quantities based on the monomer unit $C_6H_{10}O_5$ are $\Delta_r H_u^\circ$, $\Delta_r G_u^\circ$, $\Delta_r S_u^\circ$, and $\Delta_r C_{p,u}^\circ$. For cellulose having a mass fraction of water $w_{H_2O} = 0.073$, the relative molecular mass of the monomer unit is $M_r = 174.909$. For anhydrous cellulose, the relative molecular mass of the monomer unit is $M_r = 162.141$.^{a,b,c}
