1. Introduction

1,2,3-Triazole derivatives are important substructures, which can be used as unique ligands for catalysts¹ and coordination chemistry.² Triazole derivatives have found wide applications as photo-active materials³, medicine⁴, chemical sensors⁵, and thus synthesis of 1,2,3-triazoles have attracted much attention.⁶ 1,2,3-Triazole can be prepared easily via Cu-catalyzed azide-alkyne [3+2] cycloaddition reactions (Eq. 1, Scheme 1).⁷ The protocol has been widely applied to the synthesis of various triazoles, which is restricted because the commercially available terminal alkynes are limited. Recently, the construction of C-C and C-N bonds through metal-catalyzed C-H bond activation and functionalization has been made great progress.⁸ We envisioned that the C-H activation strategy would also be applicable to the synthesis of triazoles. Functionalization of triazole through triazole-directed C-H bond activation would be an economic synthetic route for complex triazole derivatives (Eq. 2).

Scheme 1. Synthesis and functionalization of triazoles

1,4,2-Dioxazol-5-ones is known to be a nitrene precursor which can generate active *N*-acyl nitrenes by losing one molecule of CO₂ when it was heated or illuminated in the presence of metal. 1,4,2-Dioxazol-5-one can be used as a nitrogen source to form C-N bonds by nitrene insertion process.⁹ We have previously reported rhodium catalyzed annulation of triazoles and internal alkynes. The reaction proceeded via sequential triazole-directed C-H activation, C-C, C-N, and C-O bond formation affording mesoionic triazolo[5,1-*a*]isoquinoliums.¹⁰ In this paper, we report cobalt-catalyzed directed C-H functionalization of 1,2,3-triazole leading to amidated triazoles in good to excellent yields.

2. Results and discussion

The experiment results showed that cobalt complex could catalyze the reaction of 1-benzyl-4-(*p*-tolyl)-1*H*-1,2,3-triazole **1a** and 3-phenyl-1,4,2-dioxazol-5-one **2a**. Initially, the reaction conditions were optimized by using the reaction of **1a** and **2a** as the model reaction, and the results were summarized in Table 1. At the loading of 10 mol% [CpCo(CO)I₂] and 20 mol% AgSbF₆ at 100 °C using 1,2-dichloroethane as the solvent, the amidation product **3a** was obtained in 64% yield (Table 1, entry 1). Further addition of acetate salts such as KOAc and NaOAc can slightly improve the reaction (entries 2 and 3). However, AgOAc showed negative effect (entry 4). When the temperature was lowered to 80 °C, the yield of the target product was decreased to 35% (entry 5). Further increase of temperature to 120 °C did not show obvious influence on the isolated yield (entry 6). For the triazole-directed amidation reaction, two equivalent of 3-phenyl-1,4,2-dioxazol-5-one **2a** is appropriate, and the use of larger amount of **2a** did not increase the yield (entry 7). Extension of reaction time did not raise the yield of **3a**, Probably longer reaction caused side

reactions (entries 8 and 9). When the loading of cobalt catalyst was increased to 15-20 mol%, **3a** could be obtained in up to 84% yield (entries 10 and 11). For comparison, in the absence of cobalt complexes, no desired product was observed (entries 12 and 14). In addition, AgSbF₆ is also essential (entry 13). Under

the same conditions, only trace amount of desired product was observed without using AgSbF₆ (entry 14). AgSbF₆ could not be replaced by AgOAc (entries 15 and 16). When 20 mol% of cobalt catalyst was used without KOAc, the yield of **3a** was decreased 73% (entry 17).

After optimization studies, we explored the feasibility of cobalt-catalyzed C–H amidation of other 1,2,3-triazole and dioxazolone derivatives. At the loading of 20 mol% of the cobalt catalyst in 1,2-dichloroethane, the amidation reaction of a number of triazoles bearing electron-withdrawing and electron-donating groups at their aromatic rings were studied. The results were summarized in Table 2. The reaction of **1b** (R₂ = H, R₂ = CH₂Ph) and **2a** afforded **3b** in 56 % yield. Triazole **1c** (R₁ = *o*-CH₃, R₂ = CH₂Ph) having a *meta* methyl showed lower activity, and the corresponding product was obtained in 64% yield. Fluorine-containing triazole are quite active, and **3d** was obtained in 86% yield in the case of 1-benzyl-4-(4-fluorophenyl)-1*H*-1,2,3-triazole, whereas the chlorine-containing triazole showed relatively lower activity. When *N*-substituent was replaced by an alkyl group, the corresponding triazoles **1f** (R₁ = H, R₂ = oct) and **1g** (R₁ = *p*-F, R₂ = oct) also reacted with dioxazolone smoothly, especially in the case of 4-(4-fluorophenyl)-1-octyl-1*H*-1,2,3-

triazole **1g** (R₁ = *p*-F, R₂ = oct), the target product was isolated in nearly quantitative yield. To fully characterize the product, single crystals of **3g** were grown by slow diffusion of hexane into

the toluene solution of **3g**. The structure of **3g** determined by X-ray diffraction was given in Figure 1.

The amidation reactions of triazoles having a *N*-phenylethyl-substituent with dioxazolone were also successful at the loading of 20 mol% of cobalt catalyst at 100 °C, and their corresponding

amidated products were isolated in 83, 90, 85, 56, and 60% yields, respectively. Finally, we examined the reactivities of dioxazolone bearing different substituents at their aromatic rings. Although the desired amidated products could be successfully obtained, the yields strongly depend on the substituents including methyl, methoxyl, and fluorine.

Table 2. Cobalt-catalyzed amidation of 1,2,3-triazole

On the basis of the previous reports,¹⁰ a plausible catalytic mechanism was proposed and depicted in Figure 1. The cobalt iodide complexes would generate $[\text{Cp}^*\text{Co}(\text{Sol})]^+$ species **I** in the presence of AgSbF_6 due to halogen abstraction and CO dissociation. Further interaction with a triazole molecule would yield **II** because of the coordination of triazole. Subsequent C-H

3. Conclusion

In conclusion, we described cobalt-catalyzed amination of various triazoles by using dioxazolones as the nitrogen source. A number of amidated triazole derivatives have been obtained in good to excellent yields. The reaction was believed to proceed via cobalt catalyzed triazole-directed C-H bond activation and subsequent nitrene insertion. The starting materials are easily available and the catalyst is cheap, thus the protocol offers a new method for the direct functionalization of triazoles.

4. Experimental section

4.1 General

All chemicals were of reagent grade quality obtained from commercial sources and used as received. All triazole were synthesized according to the reported methods. ^1H and ^{13}C NMR spectra were recorded on a Bruker Avance-400 (400 MHz) spectrometer, 400 MHz for ^1H and 100 MHz for ^{13}C . Chemical shift (δ) were expressed in ppm downfield to TMS at $\delta = 0$ ppm and coupling constants (J) were expressed in Hz. Cobalt catalyst,¹¹ 1,2,3-triazoles¹² and dioxazolones¹³ were prepared according to reported literatures.

4.2 General procedure for the amidation of triazoles

1a (0.20 mmol), **2a** (0.40 mmol), $\text{Cp}^*\text{Co}(\text{CO})\text{I}_2$ (19 mg, 0.04 mmol, 20 mol %), AgSbF_6 (27 mg, 0.08 mmol, 40 mol %), and KOAc (4.0 mg, 0.04 mmol, 20 mol %) in 1,2-dichloroethane (2 mL) were charged into an oven-dried 2 mL tube sealed with a Teflon screw cap. This sealed tube was heated at 100 °C for 24h under air. The products were purified by flash column chromatography eluting with petroleum ether/ethyl acetate.

HOAc afforded cobaltacyclic complex **III**. Interaction of 1,4,2-dioxazol-5-one **2** with **III** generates Co(III) amido species **IV** with the release of CO_2 and following nitrene insertion. Protonation of **IV** would yield the target product and regenerate the active cobalt species.
