Abstract

We employ code-switching (the alternation of two languages in bilingual communication) to test the hypothesis, derived from experience-based models of processing (e.g., Boland, Tanenhaus, Carlson, & Garnsey, 1989; Gennari & MacDonald, 2009), that bilinguals are sensitive to the combinatorial distributional patterns derived from production and that they use this information to guide processing during the comprehension of code-switched sentences. An analysis of spontaneous bilingual speech confirmed the existence of production asymmetries involving two auxiliary+participle phrases in Spanish-English code-switches. A subsequent eye-tracking study with two groups of bilingual code-switchers examined the consequences of the differences in distributional patterns found in the corpus study for comprehension. Participants' comprehension costs mirrored the production patterns found in the corpus study. Findings are discussed in terms of the constraints that may be responsible for the distributional patterns in code-switching production and are situated within recent proposals of the links between production and comprehension.

Introduction

A hallmark of proficiency in two languages is code-switching (the alternating use of two languages in bilingual speech). Proficient bilinguals often code-switch in the midst of speaking with or writing to other bilinguals. The following email illustrates the point clearly (code-switched material appears in bold and capital letters for ease of presentation; translation appears in square brackets).

For several decades, code-switching was regarded as random interference of one language with the other (e.g., Lance, 1975). We now know that code-switching is rule-governed (e.g., Deuchar, Muysken, & Wang, 2007; MacSwan, 2000; Myers-Scotton, 2002; Toribio, 2001), although there is little agreement on the precise nature of the rules involved. There is consensus, however, as to the observation that code-switching is a remarkable feat of bilingual communication that gives language scientists the potential to understand how humans negotiate the boundaries of two languages (e.g., Kroll, Dussias, Bice, & Perrotti, 2015; Kroll, Dussias, Bogulski, & Valdés Kroff, 2012).

Code-switching presents a unique cognitive puzzle on the link between production and comprehension. In particular, the production of code-switched speech is putatively under the control of bilingual speakers, as evidenced by their ability to speak in one language when necessary (e.g., when speaking to a monolingual conversational partner). Yet bilingual comprehenders do not *a priori* know when a code-switch will occur in speech. In this sense, switches can be unexpected and, thus, potentially more difficult to process than within-language sentences. In support of this, several studies on the comprehension of code-switched language have documented costs associated with processing code-switches (e.g., Altarriba, Kroll, Sholl, & Rayner, 1996; Bultena, Dijkstra, & Van Hell, in press; Proverbio, Leoni, & Zani, 2004). Given the presence of switch costs, it is on the surface surprising that bilinguals rarely report experiencing difficulties comprehending code-switched discourse. In fact, bilinguals often have difficulty remembering which language was used in any particular speech exchange (Gumperz, 1982) and are often not able to unequivocally indicate the precise locus of a recently produced code-switch (Toribio, 2001). These facts suggest the existence of factors that mitigate switch costs. This logic resonates with what has been proposed in many studies of monolingual syntactic ambiguity resolution: the observation that readers garden-path only occasionally, even though temporary ambiguities are common, indicates that they use cues from production to guide their initial choices (e.g., Garnsey, Pearlmutter, Myers, & Lotocky, 1997).

The main goal of the work presented here is to test the hypothesis, derived from experience-based models of processing (represented in the work of, e.g., Boland, Tanenhaus, Carlson, & Garnsey, 1989; Britt, 1994; Gennari & MacDonald, 2009; Holmes, Stowe, &

Cupples, 1989; MacDonald, Pearlmutter, & Seidenberg, 1994; McRae, Hare, Elman, & Ferretti, 2005; Novick, Thompson-Schill, & Trueswell, 2008; Pickering & Garrod, 2013), that bilinguals are sensitive to the combinatorial distributional patterns derived from production and that they use this information to guide processing during the comprehension of code-switched sentences. As will be shown below, our approach exploits the power of the unique linguistic environment in which bilinguals find themselves to reveal the central influence of production and its relationship to the linguistic representations that speakers recruit during comprehension (e.g., Dell & Chang, 2014; Levy, 2008). A second aim is to add bilingualism to the discussion of how language production affects language comprehension with the purpose of broadening the evidential base. The evidence in favor of experience-based models of processing has largely come from studies with monolingual speakers, and predominantly from studies on syntactic ambiguity resolution or the interpretation of subject/object relative clauses. Given the demographic reality that more speakers around the world are bilingual, bilingualism can and should be used as a tool to uncover important aspects of language function that may be obscured or difficult to study when examining the behavior of individuals who speak only one language (see Kroll, Bobb, & Hoshino, 2014). In the work reported here, we use the presence of code-switching in bilingual communities to test the correspondence between production patterns and comprehension difficulty proposed in experience-based models of language processing.

Switch costs

An important distinction in the code-switching literature is the division between inter-

100 sentential and intra-sentential switches. Inter-sentential code-switches take place at sentence
101 boundaries, as in example 1, and intra-sentential switches occur within sentence boundaries, as in
102 example 2 (in both examples, Spanish words appear in italics; the underlined portion comprises
103 the switch).

104 (1) I need to go to the pharmacy. *Tengo que comprar aspirina.*

105 ‘...(I) have to buy aspirin.’

106 (2) *Mi tía dijo que my uncle left.*

107 ‘My aunt said that...’

108 Intra-sentential switches require greater simultaneous control of both languages, creating a
109 unique opportunity to observe the interaction between two linguistic systems. Languages across
110 the world differ in their statistical regularities even when surface structure is similar (e.g.,
111 Dussias, Marful, Gerfen, & Bajo, 2010). An open question, then, is how bilingual speakers
112 successfully navigate between two languages within the same sentence. Do bilinguals follow the
113 specific distributional statistics of one language or the other when engaged in code-switching? Or
114 do they develop knowledge of when code-switches are more likely to occur? If the interaction
115 between linguistic systems and the constraints that guide their successful integration during
116 code-switching can be systematically characterized, we propose that they provide a valuable
117 means of investigating questions concerning the relationship between sentence production and
118 comprehension.

119 Quantitative studies on intra-sentential switching involving a number of language pairs
120 have revealed that certain types of syntactic junctures are more likely to serve as the loci of code-

switching than others. If exposure-based models generalize to code-switched speech, then bilinguals are likely to use this distributional information to guide their predictions of where code-switches are more likely in comprehension. Yet most of the evidence involving switches between languages points to the existence of processing costs relative to staying within the same language. One source of evidence for switch costs has been reported in studies of language switching during lexical decision tasks. Findings from such studies (e.g., Grainger & Beauvillain, 1988; Grainger & O'Regan, 1992; Thomas & Allport, 2000; von Studnitz & Green, 1997) demonstrate that recognizing and integrating a linguistic code distinct from the code most recently encountered incurs a processing cost for the comprehender. However, the implications of these results for understanding the effect of real-world code-switched language are limited by the fact that the vast majority of these studies employ decontextualized language switching tasks involving words presented in isolation and where the target language is determined by the experimenter (but see Gollan & Ferreira, 2009), while actual code-switching in bilingual communication is an inherently discourse-based phenomenon, where the two languages of the bilingual are fully engaged, and where code-switching is entirely under the control of the speaker. Given this, the switching cost triggered by a language change in the lexical switch studies cited above might well be viewed as analogous to switch costs incurred in non-linguistic domains (e.g., Allport, Styles, & Hsieh, 1994) and not as a clear indication that code-switching in natural discourse will necessarily incur costs in the same manner (see also Myslín & Levy, in press).

Few, but important, studies have examined the consequences of sentence-level switching for comprehension and have returned a mixed set of results. Some studies have revealed that processing intra-sentential code-switches is costly. For example, in an eye-tracking reading study, Altarriba, Kroll, Sholl, and Rayner (1996) demonstrated that noun switches were fixated longer than synonymous within-language words; similarly, using event-related potentials, Proverbio, Leoni, and Zani (2004) showed longer reaction times and increased N400 amplitudes for processing code-switched words. However, other studies provide evidence that switch costs can be mitigated. For example, Moreno, Federmeier, and Kutas (2002) found that the enhanced late positivity that they observed for code-switched words was reduced when the switch was less unexpected. Chan, Chau, and Hoosain (1983) provided evidence that reading times for long stretches of mixed-language passages were the same as those for equivalent unilingual passages, suggesting that discourse-level context also facilitates the processing of code-switching. In the auditory domain, studies have also investigated how bilinguals comprehend a word when it is spoken in a language (the “non-target” or “embedded” language) that is different from the language of the preceding sentence context (e.g., Grosjean, 1988; Li, 1996; Soares & Grosjean, 1984). The results indicate that the extent of activation of the non-target alternative is modulated by phonetic cues available to the listener, such as the phonotactic structure of the code-switched target item. From these findings, it is clear that although one can isolate costs associated with code-switching, researchers have also identified conditions under which the comprehension of code-switched target items is facilitated.

In the work presented here, we test the hypothesis that bilingual comprehenders exploit

potential cues rooted in their linguistic experience with code-switched constructions to facilitate the comprehension of upcoming other-language items. Cues can be present at multiple linguistic levels. For example, they exist as subtle low-level cues, such as slight changes in VOT before a code-switch (e.g., Balukas & Koops, 2015; Fricke, Kroll, & Dussias, 2015) and slow speech rate (Fricke et al., 2015); they may also be discourse-driven such that certain topics are more likely than others to elicit code-switches (e.g., Myers-Scotton, 1993). In addition, code-switches may be used as a strategy among bilinguals to more saliently encode for meanings of low predictability and high information content (Myslín & Levy, in press). Here we examine whether experience with patterns of code-switching in production prepares the comprehender for the relative likelihood of encountering a code-switch in a given context. Our hypothesis is that bilinguals who are exposed to code-switching are able to extract patterns of likely code-switches from the exemplars of bilingual utterances in their community; these patterns, in turn, become reliable indicators of when code-switches are more likely to occur in the speech of their interlocutors. If bilinguals can successfully tap into knowledge about statistical regularities in the production of code-switched speech, then they should be able to exploit this knowledge to facilitate the comprehension of code-switched language, which should reduce or eliminate switch costs. Findings such as these would suggest sensitivity to production statistics in comprehension and would be congenial with proposals highlighting that exposure-based factors guide readers' comprehension (Bybee, 2013; Goldberg, 2006; Langacker 1987; MacDonald, 1999, 2013; MacDonald & Seidenberg, 2006).

Production asymmetries in code-switched speech

We capitalize on the presence of production asymmetries in code-switched discourse to examine the relationship between production and comprehension. Of particular relevance for our purposes, several studies examining the production of Spanish-English intra-sentential code-switches (e.g., Lipski, 1978; Pfaff, 1979; Poplack, 1980) have documented an asymmetry involving alternations within the auxiliary phrase—the structure under investigation in the current study. Specifically, code-switching into an English participle preceded by the Spanish auxiliary *estar* ‘be’ (e.g., *los niños están cleaning their rooms* ‘the children are ...’) occurs as frequently in corpora as code-switches in which both the auxiliary and the participle appear in English (e.g., *los niños are cleaning their rooms*). However, code-switches into an English participle preceded by the Spanish perfect auxiliary *haber* ‘have’ (e.g., *los niños han cleaned their rooms* ‘the children have...’) are considerably less frequent than code-switches in which both the auxiliary and the participle appear in English (e.g., *los niños have cleaned their rooms*). The preponderance of switches involving progressive structures over perfect structures illustrates the differential behavior of these two switches in bilingual production. Importantly, the differences in distributional probabilities of these code-switches reflect differences in syntactic probabilities and not differences in meaning biases. That is, although the progressive and perfect forms inherently convey different temporal meanings, whether a code-switch is produced at the verb phrase boundary (i.e., at the auxiliary) or at the participle (i.e., immediately following the auxiliary) does not change the meaning of the utterance. In other words, ‘*los niños are cleaning their rooms*’ means exactly the same thing as ‘*los niños están cleaning their rooms*’ and ‘*los*

204 *niños* have cleaned their rooms’ means the same as ‘*los niños* han cleaned their rooms.’ This is
205 an important point when examining the predictions of models arguing that frequency of exposure
206 to certain constructions is a major factor guiding sentence comprehension (e.g., Jurafsky, 1996;
207 MacDonald & Seidenberg, 2006). Because the two variants (e.g., ‘are cleaning’ and ‘*están*
208 cleaning’) do not differ in meaning, findings that show frequency effects in comprehension can
209 be more readily attributed to particular distributional patterns in code-switched speech than to the
210 meaning conveyed by the structures themselves.

211 We will address possible reasons for the distributional patterns in production of these two
212 types of code-switches in the next section, but the critical point here is that these code-switches
213 have been reported in a variety of corpus studies to occur with different frequency. As mentioned
214 earlier, growing evidence from experience-based studies of sentence processing indicates that
215 frequency of exposure to certain word combinations modulates comprehension difficulty.
216 Whether such correspondences between comprehension and production extend to code-switching
217 is an empirical question, but the results from monolingual research lead us to predict that the
218 differential probability of producing a code-switch at a participle when it is preceded by the
219 auxiliary *estar* and by the auxiliary *haber* will result in different behaviors when bilinguals
220 comprehend these two types of code-switched structures. Participants are predicted to process
221 switches at the auxiliary and those at the participle involving the progressive structure similarly.
222 However, when the perfect structure is involved, switches at the auxiliary should incur less
223 processing disruptions relative to switches at the participle.

224

225 *Why production patterns look the way they do*

226 One proposal that captures production asymmetries in code-switching is the 4-M model
227 (Myers-Scotton, 1993; Myers-Scotton & Jake, 2001). The model takes as a starting point the
228 observation of a general constraint on the “switchability” of closed-class items (e.g., determiners,
229 some prepositions, complementizers, etc.). From a psycholinguistic perspective, this observation
230 is of interest because the differential behavior of closed-class words relative to open-class words
231 has been noted in various aspects of monolingual production: (a) certain types of speech errors
232 strand closed-class items; (b) closed-class categories resist loss or incorporation of new words;
233 (c) in lexical decision, closed-class, but not open-class, items show frequency-independent
234 behavior; (d) work on aphasia has shown that open- and closed-class items are differentially
235 affected (e.g., Bradley, Garrett, & Zurif, 1979; Joshi, 1985). Although it is generally
236 uncontroversial that closed-class words resist code-switching, researchers have noted some
237 puzzling exceptions. To illustrate, whereas some prepositions resist switching (e.g., the object-
238 marker preposition *a* ‘to’ in Spanish), others switch freely (e.g., prepositions that assign theta
239 roles, such as Spanish *con* ‘with’). The 4-M model portrays the differential participation of
240 closed-class items in code-switching, and the concomitant production asymmetries, by
241 classifying closed-class items in terms of their empirically-evident syntactic roles and of
242 hypotheses regarding how and when they are retrieved in language production. The basic insight
243 is that not all closed-class items are equal. So-called “early system morphemes” (e.g., theta-role
244 assigning prepositions, determiners, some auxiliaries) are salient at the level of the
245 conceptualizer (in terms of Levelt’s 1989 speech production model) and, thus, free to participate

in code-switching. Conversely, “late system morphemes” (e.g., case affixes in some languages, morphemes marking subject or object agreement, some auxiliaries, case marking prepositions) are structurally assigned and, hence, not salient until later during language production (where grammatical encoding takes place). Because of this, they do not easily participate in code-switching.

With respect to the structures examined in this study, the model inherently predicts code-switching asymmetries in production, given that the auxiliary *estar*, and early system morpheme, is retrieved at a different stage during sentence planning than *haber*, a late system morpheme. By locating late system morphemes in the syntactic frame, the proposal links their retrieval to syntactic processing, in contrast to content and early selection morphemes, which are more dependent on semantic information and are retrieved earlier. If this analysis is correct, *estar* should be salient at the level of the mental lexicon, and switches involving the *estar*+English participle structure should have no particular restrictions on their production. Conversely, because *haber* functions as a placeholder in Spanish (i.e., it is void of meaning) for the expression of grammatical features, the well-formedness requirements of Spanish oblige *haber* to appear in participial structures; therefore, the entire *haber*+participle phrase is salient at a later stage in the retrieval process, when late system morphemes are structurally-assigned in the syntactic frame. This later retrieval, then, restricts code-switches between *haber* and an English participle (We return to the 4-M model in the General discussion).

The paper is structured as follows. In the next section, we report the findings of a corpus study conducted to confirm the differences reported in past code-switching literature regarding

267 the production asymmetries discussed above. Then, we present the results of an eye-tracking
268 experiment that examined the consequences of the differences in distributional patterns found in
269 the corpus study for the comprehension of code-switched sentences. We investigate this question
270 with two groups of Spanish-English bilinguals: one group exposed to code-switched speech early
271 in life and another group exposed to code-switching later in life (during late adolescence or
272 adulthood). We predicted the following. If frequently produced code-switch types are processed
273 with more ease than less frequent ones, then *haber*+English participle switches (e.g., *los niños*
274 *han cleaned* ‘the children have...’) should produce longer reading times than their corresponding
275 phrasal boundary switches (e.g., *los niños* *have cleaned*). However, there should not be reading
276 time differences between *estar*+English participle switches (e.g., *los niños* *están cleaning* ‘the
277 children are...’) and their corresponding phrasal boundary switches (e.g., *los niños* *are cleaning*)
278 because both types of code-switches are found in spoken and written corpora with approximately
279 the same frequency of occurrence. In addition, if the amount of previous exposure to and use of
280 code-switching influences comprehension costs of code-switched sentences, then the early
281 exposure group and the late exposure group should display different reading times at the code-
282 switched region under examination. Specifically, because of their increased experience with the
283 second language and, potentially, with code-switching, the early exposure group’s fixation
284 durations should better reflect the code-switching patterns found in naturalistic production
285 corpora, when compared to those of the late exposure group. We end with a general discussion of
286 our results.

287

288

289 **Corpus study**

290 Code-switching may or may not be a community discourse mode (Poplack, 1980). When
291 it is, it is produced alongside copious stretches of unilingual discourse. This means that there are
292 no code-switching corpora per se; instead bilinguals speak to other bilinguals using stretches of
293 discourse in one of their two languages, with single-word or multi-word code-switches
294 interspersed. A good example of this is the Bangor Miami Corpus of English-Spanish
295 Codeswitching (Deuchar, Davies, Herring, Parafita Couto, & Carter (2014). The corpus is made
296 up of approximately 43,327 utterances collected during 35 hours of bilingual speech. Of these,
297 26,801 utterances are unilingual English, 13,999 are unilingual Spanish, and 2,527 are code-
298 switched. Major categories, such as single nouns, together with subject noun phrases, object
299 noun phrases, and subordinate clauses most often participate in intra-sentential code-switching,
300 leaving a relatively small opportunity to observe code-switches at other syntactic sites, including
301 switches at the auxiliary phrase. As a way of illustration, 510 (60%) of the intra-sentential code-
302 switches reported by Poplack (1980) involved major constituents, whereas only 59 switches
303 (6.9%) involving the auxiliary phrase were observed. This does not mean that generalizations
304 extracted from a small number of code-switches are not valid. The “Equivalence Constraint”
305 (Poplack, 1980), arguably one of the constraints on grammatical code-switching that has stood
306 the test of time, was based on only 851 intra-sentential code-switched utterances gathered during
307 66 hours of bilingual recordings. What it means, though, is that generalizations derived from one
308 code-switching corpus need to be supported through the examination of other corpora. The

corpus study presented below, therefore, was carried out to corroborate the production patterns described in earlier work.

We examined available oral and written Spanish-English code-switching corpora to confirm the distributional patterns involving switches at the two syntactic sites under investigation here: Spanish *estar*+English participle and Spanish *haber*+English participle. The oral corpus examined was the Bangor Miami corpus (Deuchar et al., 2014); the corpus consists of recordings of informal conversations between pairs of Spanish-English bilingual speakers living in Miami, Florida (collected in 2008).¹ Twenty-six transcriptions (approximately 390,000 words) that are available on Talkbank (<http://talkbank.org/browser/index.php?url=BilingBank/Bangor/Miami/>) were examined. The written corpus was extracted from a weekly editorial column entitled *La Calentita: Gibraltar's National Dish*, which is included in the online version of the Gibraltar newspaper, *Panorama* (<http://www.panorama.gi>). This newspaper column is written in informal language, it mimics a conversation between two women who review the country's current events, and it includes numerous instances of Spanish-English code-switching, matching the popular and frequent use of code-switching amongst locals, which they refer to as *llanito* (Moyer, 1995). Eighty-eight editorial column entries that appeared between 2004 and 2011 (approximately 25,300 words) were examined. Despite obvious differences between written and spoken language, the data extracted from the Miami and the Gibraltar corpora displayed similar switching patterns. Moreover, in her comparison of oral and written Gibraltarian code-switches, Moyer (1995) reported patterns of code-switches that were similar to

¹ A detailed description of the corpus, recruitment methods, data collection, and data transcription can be found in Deuchar et al. (2014).

those described by Lipski (1985), Pfaff (1979), and Poplack (1980) for U.S. bilingual communities. Importantly, our corpus analysis confirmed a claim made in past code-switching literature: during code-switched speech, switches at the auxiliary and at the participle occur with similar frequency when the verbal bundle comprises the progressive structure, but when it involves the perfect structure, switches at the former site are much more frequent than those at the latter site.

Extraction and coding procedure

For the analysis, we searched the transcriptions and the editorial column entries for instances of the progressive structure (i.e., the Spanish auxiliary *estar* and the English auxiliary *be* in its full or contracted form followed by a present participle) and the perfect structure (i.e., the Spanish auxiliary *haber* and the English auxiliary *have* in its full or contracted form followed by a past participle). In the written corpus, sentence boundaries were divided by periods. In the oral corpus, instances in which the transcriptions lacked punctuation that clearly demarcated the beginning and end of sentences were treated following a conventional procedure in sociolinguistic research whereby the entire conversational turn of a participant is defined as a sentence. All grammatical subjects for the progressive and perfect structures were included in the analysis (e.g., noun phrases and pronouns, all grammatical persons, animate and inanimate subjects, individual and collective subjects), as well as all types of sentences (e.g., declarative and interrogative, affirmative and negative). Finally, the progressive and perfect structures were

included with auxiliary forms in the present, past, and future tenses and the indicative and subjunctive moods.

After the initial extraction from both corpora, the following four criteria were applied to the sample. Tokens of the progressive structure were excluded if they referred to a future action (e.g., “I’m leaving on Friday”). The use of the progressive structure to signal future only exists in English; in Spanish the future is expressed with simple future or periphrastic future constructions. Because this particular use of the progressive structure could be considered an environment in which a code-switch might be blocked due to lack of equivalence across languages, all instances were excluded. In the case of the oral corpus, tokens were also eliminated if the auxiliary was not pronounced and, therefore, not spelled out in the transcriptions (e.g., “...because they offering him a big salary”). In addition, tokens were excluded when they contained the perfect structure with the past participle of the verb *get* because these phrases carried a possession meaning instead of a past action meaning (e.g., “and then he’s got this black and blue bruise”). Finally, tokens that comprised idioms or fixed phrases with either the progressive or the perfect structure (e.g., “You are telling me, Cynthia *de mi corazón*” ‘...of my heart’) were eliminated from further analysis. In all, 36 tokens were excluded from the analysis, representing less than 3% of the data. From the remaining tokens, we selected only those that contained a code-switch somewhere in the sentence—in other words, sentences that included both Spanish and English words. These code-switched sentences constituted the code-switched corpus for the analysis. For each sentence or conversational turn, code-switches with the progressive or perfect structure were coded for whether they occurred immediately

before or immediately after the auxiliary phrase, at the auxiliary, at the participle, or elsewhere in the sentence.

Results

After applying the criteria for exclusion, 845 sentences with the progressive structure and 375 sentences with the perfect structure were extracted from the Miami oral corpus. An additional 142 sentences with the progressive structure and 183 sentences with the perfect structure were extracted from the Gibraltar written corpus. Because the main goal of the corpus study was to verify the distributional patterns of code-switches reported in past code-switching studies (e.g., Pfaff, 1979) involving the two structures, the data analyzed included only the subset of sentences in which a code-switch was instantiated from Spanish to English. In the following section, processing difficulty is assessed on switches going in this direction only. Table 1 displays the distribution of code-switches by syntactic position.

<Insert Table 1 here>

As shown in Table 1, there were numerically more code-switches involving the progressive and perfect structures in the written corpus (106 and 150, respectively) than in the oral corpus (93 and 28, respectively). In the written corpus, the code-switched tokens represented approximately 79% of the total number of the extracted sentences, while in the oral corpus they constituted a little less than 10% of the data. This difference is not surprising given that the editorial column from Gibraltar was written with frequent code-switching by design; in contrast, the oral corpus is a collection of conversations that took place between bilingual speakers. In

391 compiling the corpus, the researchers simply asked the bilingual participants to speak as they
392 normally would, without explicit reference to code-switching (see Deuchar et al., 2014).
393 Whereas the number of code-switches involving the progressive structure was similar between
394 the two types of corpora (93 tokens in the oral corpus and 106 in the written corpus), there were
395 more code-switches involving the perfect structure in the written corpus (150 tokens) than in the
396 oral corpus (28 tokens), likely reflecting the topics discussed in each type of corpus. These
397 differences aside, the oral and written corpora show remarkable overlap with respect to the
398 distribution of the switch locations examined here. When the progressive structure was involved,
399 switches were just as likely to occur at the participle (e.g., *los niños están cleaning...* ‘the
400 children are...’) as switches at the auxiliary (e.g., *los niños are cleaning...*).

401 In the oral corpus, seven sentences included a switch at the progressive auxiliary and
402 another seven included a switch at the present participle, each of these representing 7.53% of the
403 code-switched data. Therefore, a switch was as likely to occur at the auxiliary as it was to occur
404 at the present participle. However, turning to sentences with the perfect structure, three (10.71%)
405 included a switch at the perfect auxiliary and none included a switch at the past participle. In the
406 written corpus, a very similar picture emerges. In this case, eight sentences included a switch at
407 the *estar* auxiliary and an additional eight sentences included a switch at the present participle,
408 each of these representing 7.55% of the code-switched data. Thus, the results of the written
409 corpus confirm that a switch at the *estar* auxiliary and a switch at the present participle are
410 equally probable. These percentages of occurrence are strikingly similar across the two corpora.
411 Regarding the sentences that included the perfect structure, in 15 of them, the switch occurred at

the *haber* auxiliary, representing 10% of the code-switched data, and there was one occurrence of a switch at the past participle. Once again, these results closely resemble those in the oral corpus.

It is also worth noting that the particular examples of switches at the present participle are similar across both corpora. In oral and written form, there are cases in which the *estar* auxiliary and the English present participle are adjacent to each other and other cases in which there is intervening linguistic material. In addition, in both corpora the code-switched progressive structure appeared with varied grammatical subjects (i.e., noun phrases, pronouns, omitted subjects) and the *estar* auxiliary appeared in different tenses (i.e., present, past).

In order to confirm these numerical trends, we conducted Fisher's exact tests (due to our small sample sizes) on the production distributions for each auxiliary+participle form to test whether the distributions were significantly different from each other across the oral and written corpora. For both the progressive and perfect structures, there were no significant differences in production distributions across the two corpora (progressive structure, $p = 0.55$; perfect structure, $p = 0.89$). Consequently, we combined the tokens from the oral and written corpora for the code-switches at the auxiliary (e.g., *los niños are cleaning...*) and those at the participle (e.g., *los niños están cleaning...*). To test whether present or perfect structure code-switches are equally likely to be produced at the auxiliary or at the participle, we performed binomial tests on the success of producing code-switches at the auxiliary (out of tokens comprising code-switches at the auxiliary and at the participle) at more than 50% probability. The production of code-switches at the auxiliary involving the progressive structure is not significantly greater than 50% (15/30, $p =$

0.57). In contrast, the production of code-switches at the auxiliary involving the perfect structure is significantly greater than 50% (17/18, $p < 0.001$).

These results reveal that *estar*+participle switches are more frequently found in natural oral and written production corpora than *haber*+participle switches. According to these data, Spanish-English bilinguals seem to be equally likely to switch at the auxiliary or at the present participle when using the progressive structure. However, when using the perfect form, they avoid switching at the past participle. Instead, they switch at the auxiliary or right after the past participle. In all, our findings confirm the asymmetric distribution of *estar*+participle switches and *haber*+participle switches reported in past studies (Lipski, 1978, 1985; Pfaff, 1979; Poplack, 1980).

Eye-tracking study

Taking into consideration the differences in distributional patterns found in our corpus study for the two types of switches examined here, we conducted an eye-tracking study to investigate the consequences of these differences for the comprehension of code-switched sentences. The specific purpose of the eye-tracking study was to examine if the type of code-switch that is more frequently found in naturalistic production (i.e., a switch at the participle involving the progressive structure) is processed with more ease than the type of code-switch that is rarely found in code-switching corpora (i.e., a switch at the participle involving the perfect structure).

Methods

Participants

Two groups of Spanish-English bilinguals were recruited. One group (early exposure group, $n=42$) had acquired Spanish and English in early childhood and had been exposed to Spanish-English code-switching since childhood by virtue of being born, being raised, and living in an established Spanish-English code-switching community in Harlem, New York (NY; see Poplack, 1980). The second group of participants (late exposure group, $n=27$) was comprised by speakers from Hispanic countries who had immigrated to the United States (US) later in life (mean age of arrival = 18). The majority ($n = 17$) of the participants in the late exposure group were living in the same code-switching community in Harlem. Additionally, we included ten participants in this group who did not live in Harlem, but whose linguistic profile and experience with code-switching were similar to the NY late exposure group (self-reported ratings and proficiency measures, all $ps > 0.307$). Although they had been living in the US for less time, the participants in the second group had been exposed to Spanish-English code-switching from the moment of arrival in the US. Exposure-based accounts of language processing (e.g., MacDonald & Seidenberg, 2006) suggest that less experience with particular linguistic structures will result in less sensitivity to the distributional patterns of these structures during comprehension. However, the amount of previous exposure that is required to exhibit this sensitivity during comprehension has not yet been addressed. The purpose of including this late exposure group, then, was to ascertain the extent to which amount of time spent living in an established code-

switching community (and potentially exposed to Spanish-English code-switching) affected speakers' sensitivity to distributional differences in code-switching production. In other words, we wanted to see if the results obtained with the group of participants who had been exposed to code-switching for all or most of their lives could be replicated with a group of participants who had been exposed to code-switching in the same community for less time.

All participants were undergraduate or graduate students from the City College of New York or from Penn State University. Despite differences in their amount of exposure to code-switching, all participants reported frequently engaging in Spanish-English code-switching with other bilinguals in their adult lives, both in the spoken and the written (emails, instant messages, text messages, chats) modalities. The excerpt included in the Introduction was taken from an email written by a bilingual participant from this study. It serves to illustrate that code-switching is present, not only in their oral exchanges, but also in these bilinguals' written interactions and, thus, in their reading experience. The participants in both groups completed a series of measures of language proficiency, described below.

Language History Questionnaire

In an online Language History Questionnaire (LHQ), participants provided self-ratings of their English and Spanish proficiency across reading and writing production as well as speaking and listening comprehension. They used a scale in which 1 corresponded to "very low" and 10 corresponded to "perfect." They also answered open-ended and multiple-choice questions about their history with both languages, their language acquisition experiences, and their daily

exposure to and use of both languages. Several examples of the questions asked in the LHQ are displayed in Figure 1.

<Insert Figure 1 here>

Boston Naming Vocabulary Test

As a measure of lexical access, vocabulary size, and naming performance, participants completed the Boston Naming Vocabulary Test (BNT; Kaplan, Goodglass, & Weintraub, 1983) in English and Spanish. The BNT contains 60 outline drawings of objects and animals. The images were divided into two language blocks (an English block and a Spanish block) of 30 images each. Participants completed the BNT in their self-reported dominant language first, and then in the other language. In each language block, participants were asked to name the images as quickly and as accurately as possible. The drawings were presented in order of increasing difficulty, starting with easy, high-frequency words, such as *flower* and *cama* ('bed') and concluding with more difficult, low-frequency words like *protractor* and *yunta* ('yoke'). Participants' responses to the BNT were digitally recorded and these recordings were then reviewed to score the test. Participants received a score of 1 for every correctly named image and 0 for every incorrectly named image or for any unnamed image.

Grammar tests

Participants also completed the grammar sections of the Michigan English Language Institute College Entrance Test (MELICET) and the Advanced Test of the Diplomas de Español

como Lengua Extranjera (DELE, ‘Diplomas of Spanish as a Foreign Language’). The MELICET is an advanced level English language test created by the University of Michigan English Language Institute (<http://www.michigan-proficiency-exams.com/melicet.html>) to examine ability in different English language areas. It is primarily used to test nonnative speakers of English by educational institutions as an admissions or placement test. The DELE is a standardized test of Spanish issued by the Ministry of Education, Culture, and Sport of Spain, which assesses proficiency in Spanish at seven levels (<http://diplomas.cervantes.es/en>). The test administered here was the *Nivel Superior C2*, the highest level of accreditation. Each grammar test contained 50 multiple-choice items, which evaluated grammar, vocabulary, and reading competence in isolated sentences, as well as longer stretches of discourse. An example of an item from each test is presented in Table 2. Participants received one point for each correct answer and no points for incorrect answers.

<Insert Table 2 here>

All participants were proficient in English and Spanish and they reported regular use of and exposure to both languages in the oral and written modes. More specific participant characteristics are displayed in Table 3.

<Insert Table 3 here>

Table 3 shows that both groups are very similar in terms of mean age. Within-group comparisons were conducted to explore differences between the participants’ proficiency levels in both languages. Results of paired-samples *t* tests for the early exposure participants displayed higher self-ratings and scores for English (self-ratings: $t(41) = 3.62, p < .001$; BNT score: $t(41) = 5.38$,

$p < .001$; grammar test score: $t(41) = 4.59, p < .001$). Conversely, results for the late exposure bilinguals displayed higher self-ratings and scores for Spanish (self-ratings: $t(26) = 5.43, p < .001$; BNT score: $t(26) = 5.47, p < .001$; grammar test score: $t(26) = 2.15, p = .041$). These results demonstrate that the early exposure group was English-dominant while the late exposure group was Spanish-dominant, a finding that is expected given that the former group had been immersed in an English-speaking environment since birth, whereas the latter group had lived in a Spanish-speaking environment and had received schooling in Spanish before coming to the US.

Between-group comparisons were also conducted; the results of several independent-samples t tests showed significant differences between both groups for almost all the proficiency measures displayed in Table 3 (self-ratings for English proficiency: $t(67) = 2.33, p = .023$; self-ratings for Spanish proficiency: $t(67) = -4.53, p < .001$; BNT score for English: $t(67) = 3.27, p = .002$; BNT score for Spanish: $t(67) = -7.89, p < .001$; DELE score: $t(67) = -6.11, p < .001$). The exception was the MELICET score, for which no significant difference between these two groups was found, $t(67) = -.036, p = .719$. Overall, then, the two groups are proficient in both languages, and display differences that are expected given their language histories and language dominance.

Materials and Design

The experimental stimuli comprised 48 item sets (see the Appendix) for a total of 192 experimental sentences. Each item set consisted of four different versions of the same sentence, corresponding to the four experimental conditions. Conditions 1 and 2 were code-switched

conditions with the progressive structure. In Condition 1, the switch occurred at the phrasal boundary (that is, at the auxiliary) and in Condition 2, it occurred at the participle. Conditions 3 and 4 were analogous to Conditions 1 and 2, but involved the perfect structure instead. In each experimental sentence, the critical code-switched region under examination was part of an embedded phrase to ensure its appearance in the middle of the sentence and, thus, in the middle of the computer screen. Table 4 displays a sample item set (the critical region is underlined).

<Insert Table 4 here>

In addition to the experimental items, 32 filler sentences were added. The fillers were similar to the experimental items in terms of overall length, but differed from them regarding the syntactic structures and the code-switch types included. Three examples of the fillers are provided below.

(3) Switch between the verb and the direct object

Laura estaba limpiando the kitchen before going out with her friends.

‘Laura was cleaning...’

(4) Switch between the definite article and the noun

Tomás y su esposa ya habían visto el movie that their friends had recommended.

‘Thomas and his wife had already seen the...’

(5) Switch between clauses

Como la maestra ha sospechado, the students have not studied for the exam.

‘As the teacher has suspected...’

Five practice items were added at the beginning of the experiment to familiarize participants with

the requirements of the task and the type of stimuli.

The experimental sentences were tightly controlled in several ways to ensure that extraneous factors were not responsible for the predicted pattern of results. First, the experimental stimuli were controlled for word length (mean word length 13 [range 11-14]). In addition, the verb of the main clause was always a sentential complement-biased verb or an equi-biased verb, but never a direct object biased verb; this was done to facilitate processing of the following embedded clause. Also, the grammatical subjects of the verbs in the embedded clause (mean character length 10 [range 5-14]; mean lexical frequency 27.64 [range 1-162]²) were always a cognate noun in Spanish and English (e.g., *turistas* in the examples in Table 4) in order to maximize cross-linguistic lexical activation. The participles in the critical region (mean character length of the present participles 9 [range 6-11]; mean lexical frequency of the present participles 16.03 [range 1-76]; mean character length of the past participles 8 [range 5-10]; mean lexical frequency of the past participles 51.68 [range 3-401]³) were from regular-ending verbs in order to keep the spelling of the participles as uniform as possible.

All the sentences were followed by a comprehension question (e.g., for the items in Table 4, it was “Do the tourists seem unsatisfied?”). This was done to guarantee that participants were performing the reading task as expected. Because the sentences always began in Spanish and ended in English, the comprehension questions were presented in English to avoid introducing an

² Lexical frequencies for the Spanish grammatical subjects of the embedded clauses are from the Alameda and Cuetos (1995) two-million-word corpus, and they were obtained through the Normas e índices de interés en Psicología Experimental (NIPE) website (Díez, Fernández, & Alonso, 2006).

³ Lexical frequencies for the participles of the embedded clauses are from the HAL frequency norms (Lund & Burgess, 1996), based on one million words, and they were obtained through The English Lexicon Project website (Balota et al., 2007).

inter-sentential code-switch while participants were processing the question. Half of the questions required a “yes” answer and the other half required a “no” answer. Questions were distributed evenly such that half required a response that referenced the beginning of the sentence and the other half required a response that related to the end of the sentence. Six 69-item lists were created, each containing 32 experimental items (eight for each condition), 32 fillers, and the five practice sentences. Each list contained exactly one version of each of the 48 experimental sentence item sets. Within each file, eight item blocks were created, each containing eight sentences (four experimental items and four fillers). The blocks as well as the experimental items included in each block were presented in random order to each participant with the constraint that no two sentences representing the same condition were presented immediately following one another. This resulted in the items being presented to each participant in a different order, yet the items belonging to each stimulus type were evenly distributed throughout the duration of the experiment.

Procedure

Stimuli were presented on a color monitor using an EyeLink 1000 desktop-mounted eye-tracker (SR Research Ltd.) interfaced with an IBM-compatible PC. Participants sat in front of the computer screen and used a chin rest and a forehead pad to minimize head movement. Eye movements were recorded with a camera and an infrared illuminator, located at the bottom of the computer monitor. Viewing was binocular and monocular tracking of the right pupil and cornea was performed at a sampling rate of 1000 Hz. The eye-tracker was calibrated and validated for

each participant at the beginning of the experimental block and after each break to calculate overall equipment accuracy. Following calibration, eye position errors were less than 0.3°. Bilinguals were seated 60 cm away from a 20-inch CRT monitor with 1280 × 1024 pixel resolution. At the start of the experiment, participants completed a nine-point calibration and validation procedure to allow monitoring of both horizontal and vertical eye movements. At the start of each trial, a calibration point (65 pixels wide and 85 pixels tall) appeared in the left corner of the screen, where the first word would appear. When a fixation was detected in this calibration point, it disappeared and was replaced by the sentence. Sentences appeared in 14-point Consolas font and were always presented in one line of text with 3.8 characters subtending one degree of visual angle. Participants were instructed to read each sentence silently at their own pace. After reading the sentence, participants were asked to answer a comprehension question related to the content of the sentence. The questions were answered with either “yes” or “no” by pressing one of two buttons on a game pad. In addition to the eye-tracking experiment proper, participants completed the three tasks (i.e., LHQ, BNT, grammar tests) that were used to assess language background and proficiency. These tasks were completed after the eye-tracking experiment. Participants were paid \$10 per hour for their participation in the study.

Results

We report on the results of two eye-tracking reading measures for five regions of interest. In example (6) below, forward slashes indicate where the sentences were segmented for analysis:

(6) <i>El chef piensa que/</i>	<i>los turistas/</i>	<i>are/</i>	<i>enjoying/</i>	<i>the/</i>	<i>food/.....</i>
Region 1	Region 2		Region 3	Region 4	Region 5

639
640 Region 1, the sentence initial region, combined the first four words in the sentence (Det + N +
641 Main Verb + Comp). Region 2, the embedded subject (Det + N), included words 5 and 6 and
642 constituted the region immediately preceding the critical region. Analyses on Region 1 and
643 Region 2 were conducted to rule out the possibility that any differences on the critical region
644 across conditions was caused by extraneous factors prior to the critical region. Region 3, the
645 participle, was selected as the critical region because it is the point in the sentence at which the
646 participants have processed the complete auxiliary phrase. It is also the point at which all code-
647 switches, both the code-switches at the auxiliary and the code-switches at the participle, have
648 occurred. We initially included the auxiliary as a region for analysis; however, models did not
649 converge due to high levels of skipping (28% for progressive structures and 29% for perfect
650 structures). Additionally, the auxiliary always appeared as one of four forms: *están/are* for
651 progressive structures and *han/have* for perfect structures. Unsurprisingly, deficient models
652 essentially revealed that readers were affected by the length of the auxiliary: longer auxiliaries
653 (i.e., *están* and *have*) were always read more slowly than shorter ones (i.e., *are* and *han*). We also
654 analyzed the two words after the critical region (Region 4 and Region 5, respectively). Because
655 processing is not always completed by the time the eyes move, the time spent processing a word
656 (or region) can spill over to the next word (Rayner & Duffy, 1986). Therefore, analyses on
657 Regions 4 and 5 were carried out to determine whether effects not observed on the critical region
658 surfaced at a later point in the sentence and to determine whether any effects found on the critical
659 region persisted through subsequent regions.

The two eye-tracking reading measures extracted for analysis were first-pass reading time and total time. First-pass reading time is defined as the sum of all the fixations within an interest area starting with the first fixation into that interest area until the first time the participant's gaze leaves the region either to the left or to the right (Rayner, 1998).⁴ This measure was selected over first fixation duration because past work shows that both measures yield similar results (Rayner, 1998) and because first-pass reading time best captures the cognitive operations in multi-word regions. Total time represents the sum of all fixation durations in the critical region, including all regressive fixation durations on it (Rayner & Duffy, 1986).

We analyzed the two reading measures using generalized linear mixed-effects models as implemented by the lme4 package version 1.1-7 (Bates, Maechler, Boker, & Walker, 2014) in the R Environment for Statistical Computing program, version 3.1.2 (R Core Team, 2014). Fixations shorter than 80 ms were combined with a previous or subsequent fixation if they were within one character of each other. Additionally, trials for which participants incorrectly answered the comprehension question were excluded from analysis, removing 9.6% of all experimental trials. A repeated measures ANOVA with auxiliary (progressive, perfect) as a within-subjects factor and group (early exposure, late exposure) as a between-subjects factor indicated that incorrect responses to the comprehension questions were evenly distributed across auxiliary and group (Auxiliary, $F(1,66) = 2.67, p = 0.11$; Group, $F(1,66) = 1.12, p = 0.29$; Auxiliary * Group, $F(1,66) = 0.18, p = 0.67$).

⁴ On single-word regions, first-pass reading time is equivalent to the commonly reported "gaze duration" (Liversegde, Paterson, & Pickering, 1998; Traxler, Morris, & Seely, 2002).

We included Switch Position (at auxiliary, at participle), Group (early exposure code-switchers, late exposure code-switchers) and Auxiliary Type (progressive, perfect), and their interaction terms as fixed effects in the linear mixed-effects models. All factors were coded with contrast coding (-.5 for switches at the auxiliary, late exposure code-switchers, and progressive auxiliary). For the random effects structure, we first began by including random slopes for Switch Position, Auxiliary Type and their interaction as well as random intercepts on Subjects and random slopes for Switch Position and random intercepts on Items, following a maximal random effects structure justified by the design (Barr, Levy, Scheepers, & Tily, 2013). If models did not converge, then the random effects structure subsequently included the removal of the interaction between random slopes for Switch Position and random intercepts on Subjects. Finally, if this model did not converge (one model), then a subsequent model that removed random slopes for Items was used. We indicate in the table summaries when models did not include the full random effects structure and report regression coefficients (*b*) and the *t*-values for each coefficient. We report regression coefficients as significant at the .05 level for *t*-statistic values greater than or equal to 1.96 (e.g., Schotter, Bicknell, Howard, Levy, & Rayner, 2014). In the text, we solely describe the results for first-pass reading time unless the analysis with total time led to a different result.

Sentence initial and embedded subject regions (Regions 1 and 2)

On Regions 1 and 2, we compare first-pass reading time and total time of two bilingual code-switching groups before encountering the code-switched portion of the sentences. For both

regions, skipping rates ranged from 0% to 3% across all conditions and groups. For the sentence initial and the embedded subject regions, the results from the linear mixed-effects models only revealed a main effect for Group (Region 1: $b = -189.92$, $t = -2.07$; Region 2: $b = -133.67$, $t = -2.47$), indicating that the late exposure group read the initial Spanish regions more quickly than the early exposure group for both the progressive structure (Region 1: early exposure group – switches at auxiliary = 1088 ms, SE = 45.98, switches at participle = 1115 ms, SE = 36.85; late exposure group – switches at auxiliary = 891 ms, SE = 31.81, switches at participle = 873 ms, SE = 36.17; Region 2: early exposure group – switches at auxiliary = 632 ms, SE = 26.64, switches at participle = 491 ms, SE = 18.43; late exposure group – switches at auxiliary = 502 ms, SE = 16.77, switches at participle = 491 ms, SE = 18.43) and the perfect structure (Region 1: early exposure group – switches at auxiliary = 1140 ms, SE = 40.71, switches at participle = 1156 ms, SE = 48.23; late exposure group – switches at auxiliary = 828 ms, SE = 30.35, switches at participle = 889 ms, SE = 37.6; Region 2: early exposure group – switches at auxiliary = 633 ms, SE = 26.64, switches at participle = 652 ms, SE = 28.35; late exposure group – switches at auxiliary = 561 ms, SE = 21.55, switches at participle = 525 ms, SE = 21.66). Importantly, the models did not indicate any main effects or interaction with Switch Position or Auxiliary Type, suggesting no baseline differences leading up to the code-switched region. Full model outputs for both regions are reported in Tables 5 and 6.

<Insert Tables 5 and 6 here>

Critical region (Region 3)

On the critical region, we compare first-pass reading time and total time of the two participant groups when encountering code-switches that occur with progressive (i.e., *are/están*) or perfect (i.e., *have/han*) structures. Skipping rates for trials including the progressive structure averaged 4% (range: 2-7%) and those for trials including the perfect structure averaged 3% (range: 2-5%). Mean reading times and standard error for the critical region are shown in Table 7. The results of the linear mixed-effects models for the two reading time measures are included in Table 8.

<Insert Tables 7 and 8 here>

The final model revealed a Switch Position * Auxiliary Type interaction ($b = 85.18$, $t = 2.31$) and no other main effects or interactions. In order to explore this interaction further, we conducted post-hoc comparisons using Tukey's HSD as instantiated in the multcomp package version 1.4-1 in R (Hothorn, Bretz, & Westfall, 2008). The post-hoc tests revealed a significant difference between code-switches at the participle (*los turistas han enjoyed*) and code-switches at the auxiliary (*los turistas have enjoyed*) for perfect structures ($p < 0.001$). Crucially, there was no significant difference between the progressive structure code-switches ($p = 0.13$). Post-hoc tests with total time further revealed a significant difference between perfect and progressive code-switches at the participle (*los turistas están enjoying / han enjoyed*, $p < 0.001$). Mean reading times and standard errors for both reading measures are plotted in Figures 2 and 3.⁵

<Insert Figures 2 and 3 here>

⁵ Because Group was not a significant effect, we present mean reading times collapsed for group.

First and second words post-participle (Regions 4 and 5)

In the word immediately following the critical region, participants exhibited high skipping rates across all conditions (range: 44-58%), likely due to the immediately following word being a determiner or another function word.⁶ The linear mixed-effects model that included first-pass reading time as a dependent variable did not reveal any main effects or interactions (all t s < |1.63|). In contrast, the interaction between Switch Position and Auxiliary Type was significant for total time (Switch Position * Auxiliary Type: $b = 72.14$, $t = 2.27$). Post-hoc tests with Tukey's HSD indicated a significant difference between code-switches involving the perfect structure (*los turistas have enjoyed / han enjoyed*), with switches at the participle taking longer to read than switches at the auxiliary ($p < 0.001$). Additionally, code-switches at the participle involving perfect structures (*los turistas han enjoyed*) were significantly slower than those involving the progressive structure (*los turistas están enjoying*, $p < 0.001$). As in the case of the critical region, the difference between the progressive structure code-switched conditions was not significant ($p = 0.56$). Mean reading times and standard errors for the first word post-participle region are reported in Table 9 and are plotted for first-pass reading and total time in Figures 4 and 5 respectively.

<Insert Table 9 here>

⁶ We conducted a repeated measures ANOVA including Switch Position and Auxiliary Type as within-subjects factors and Group as a between-subjects factor. This test revealed a main effect for Switch Position ($F(1,66) = 5$, $p = 0.03$, $\eta^2 = 0.01$) and a marginal effect for Auxiliary Type ($F(1,66) = 3.29$, $p = 0.07$, $\eta^2 = 0.01$), indicating that participants exhibited higher skipping rates for switches at the auxiliary ($M = 55\%$) than for switches at the participle ($M = 50\%$) as well as a similar trend for progressive structures ($M = 55\%$) and perfect structures ($M = 50\%$). Although it is difficult to determine why participants exhibited differential skipping across factors, we speculate that this pattern of results reflects easier processing in conditions that exhibit higher skipping, i.e., with function words that are highly supported by their sentence context (Rayner, 1998).

<Insert Figures 4 and 5 here>

In the second word following the participle, skipping rates ranged between 9% and 11% with a mean skipping rate of 9% for sentences including the progressive structure and 10% for sentences including the perfect structure. The linear mixed-effects model only indicated a main effect for Group ($b = 45.06$, $t = 1.99$) for first-pass reading time, such that the early exposure group read this region more quickly than the late exposure group in sentences with the progressive structure (early exposure group – switches at auxiliary = 275 ms, SE = 11.55, switches at participle = 290 ms, SE = 12.08; late exposure group – switches at auxiliary = 315 ms, SE = 15.43, switches at participle = 349 ms, SE = 18.45) and in sentences with the perfect structure (early exposure group – switches at auxiliary = 273 ms, SE = 11.21, switches at participle = 293 ms, SE = 12.33; late exposure group – switches at auxiliary = 314 ms, SE = 14.06, switches at participle = 321 ms, SE = 16.82). No other main effects or interactions were significant, and the main effect for Group was not significant for total time ($b = 25.48$, $t = 0.55$, switches at auxiliary with progressive structure = 511 ms, SE = 16.65, switches at participle with progressive structure = 535 ms, SE = 20.02; switches at auxiliary with perfect structure = 525 ms, SE = 18.37, switches at participle with perfect structure = 555 ms, SE = 19.31). Full model outputs for both regions are reported in Tables 10 and 11.⁷

<Insert Tables 10 and 11 here>

⁷ We note that the results for the combined regions (i.e., one two-word region) did not reveal any significant main effects or interactions for either first-pass reading time or total time, likely indicating that the spillover interaction effect from the critical region is short-lived and that the Group effect on the second word of the post-participle region is an emergent effect.

To summarize, bilinguals demonstrated an asymmetry in how they process code-switched sentences with the perfect structure vis-à-vis code-switched sentences with the progressive structure. Specifically, in both early and late reading measures, Spanish-English bilinguals were slower while reading code-switches at the participle that involved the perfect auxiliary (*los turistas han enjoyed*) than those at the auxiliary (*los turistas have enjoyed*). This processing difficulty extended to the word immediately following the participle for total time, indicating that the processing difficulty is not short-lived, and it dissipated in the second word after the participle. Importantly, the differences in fixation durations between the two conditions are not present prior to the critical region. Analyses of pre-critical regions revealed group differences, but these reflected language dominance, i.e., the late exposure group, as Spanish-dominant speakers, read the Spanish portion of the sentences more quickly than the early exposure group, and the early exposure group, as English-dominant speakers, began to read the English portion of the sentences more quickly than the late exposure group. Results for the perfect structure are different from those for the progressive structure, in which no significant differences between switches at the auxiliary relative to switches at the participle were found in any of the five regions examined. Critically, the asymmetric behavior observed in the comprehension of the perfect and progressive code-switches reflects the statistical regularities found in code-switching corpora; this provides support for the hypothesis that bilinguals are sensitive to the way both structures are code-switched in production.

General discussion

The way that bilingual speakers fluidly navigate between languages within a conversation presents bilingual listeners with unique challenges; because bilinguals purportedly do not provide obvious and explicit signals that they are about to produce a code-switch into the other language, the comprehension of code-switches can potentially be quite difficult due to increased ambiguity between linguistic forms. Indeed, it has been established in prior work on code-switching that processing switches incurs costs, although there is also evidence that these costs can be mitigated. What, then, makes some code-switches easier for bilinguals to recognize and other code-switches more difficult? Our approach to begin to answer this question involved identifying statistical regularities that emerge in the production of code-switching, which subsequently may be informative to bilinguals during comprehension. To address this, we capitalized on a distributional asymmetry⁸ in the production of code-switches involving the auxiliary phrase: whereas the Spanish auxiliary *estar* co-occurs with English participles in code-switched speech, the Spanish auxiliary *haber* rarely does. We examined whether these statistics could provide some advantage while two groups of bilinguals (bilinguals exposed to code-switching from an early age and bilinguals first exposed to code-switching as young adults) processed the two types of code-switches during reading. Our findings indicate that for both bilingual groups, comprehension costs that surfaced during reading mirrored the production

⁸ Asymmetries like this are not unique. In Spanish-English code-switching, grammatical gender assignment also displays production asymmetries: whereas Spanish masculine pronominal modifiers appear with English nouns whose Spanish translation equivalent is masculine (el_{MASC} shoe/ el_{MASC} zapato_{MASC}) or feminine (el_{MASC} blender_{FEM}/ la_{FEM} licuadora_{FEM}), feminine pronominal modifiers only appear with English words whose Spanish translation equivalent is feminine (la_{FEM} blender_{FEM}, but not 'la_{FEM} shoe_{MASC},’ Valdés Kroff, in press; Valdés Kroff, Dussias, Gerfen, Perrotti, & Bajo, in press).

patterns found in code-switching corpora: switches at the participle were more costly when they involved *haber* plus an English participle. The fact that both groups of bilinguals behaved similarly highlights the importance of usage-based accounts of learning (Bybee, 2006), given that in these accounts language emerges not as a result of language-specific mechanisms, but through the interaction of cognition and use (Ibbotson, 2013).

One methodological aspect of our study merits some attention. Our design necessarily required that the experimental items differ in important respects. Thus, we employed structures that were entirely different (present perfect vs. present progressive); the English participles within each structure have different morphological makeups (enjoy-ed vs. enjoy-ing) and also different distributional statistics in English; the auxiliaries appeared in different languages (are-*están*-have-*han*) and differed in their morphological structure in important ways (e.g., the –a in *están* denotes the morphological class of the verb and the –n denotes person and number; the English auxiliaries are morphologically simpler). Although these differences could be a source of concern, in our view, the very fact that the results turned out in the predicted direction in spite of the differences between the two structures underscores the central role of statistics in linguistic distributions for comprehension behavior. Furthermore, as the first spillover region continued to show the same pattern of results found in the critical region (i.e., no significant difference between the progressive conditions, but a significant difference between the perfect conditions), we interpret the overall results to indicate that the difference in the perfect conditions is due to increased difficulty for code-switches at the participle.

836 *Why production asymmetries?*

837 We return to the question of what factors may be responsible for the production
838 asymmetries of the two types of code-switches observed in the corpus data. One possibility is
839 that the differences in production arise from differences in the way that the two structures are
840 used in Spanish and English. Specifically, the perfect structure can be used with deictic adverbial
841 complements (e.g., *hoy* ‘today’) in certain varieties of Spanish—particularly in Peninsular
842 varieties—to express simultaneity to the present moment; however, this use is not possible in
843 English (Markle LaMontagne, 2011). This is illustrated in examples (8) and (9).

844 (8) *Hoy he llamado a mi madre.*

845 (9) *Today I have called my mother.

846 If equivalence facilitates code-switching (Poplack, 1980, in press), the difference between the
847 perfect structure in Spanish and English may block the occurrence of a code-switch. This
848 hypothesis does not seem tenable, however, once we consider that Spanish and English also
849 display differences in the progressive structure. For example, whereas in English the present
850 progressive can be used to refer to a future action, as shown in example (10), in Spanish the use
851 of the progressive structure to signal future is barred (11). Future in Spanish is expressed either
852 with a future marker on the verb (*comer-é* ‘(I) will eat’) or with a periphrastic construction
853 (*vamos a viajar* la próxima semana ‘(we) go to [= will] travel next week’).

854 (10) Tomorrow we are eating at 1:00 p.m.

855 (11) **Mañana estamos comiendo a la 1:00 p.m.*

856 If the differences between the perfect and the progressive structures in English and Spanish
857 create environments that are not propitious for code-switches to occur, we would not expect the
858 production patterns reported in corpus studies to look the way they do. Moreover, our corpus
859 study and our eye-tracking experiment included only cases where the two languages could
860 combine at any level of linguistic structure and use, and where the consequences of such
861 combinations did not result in semantic incompatibilities between the two languages.

862 If there are no differences in meaning or in use linked to the occurrence of code-switches
863 involving the progressive and the perfect structures, how can we explain the differences in their
864 distributional patterns? The 4-M model of code-switching (Myers-Scotton & Jake, 2001),
865 explained briefly in the *Introduction*, discusses the differential participation of closed-class items
866 in code-switching, and the resulting production asymmetries, by classifying closed-class items
867 (including auxiliaries) in terms of how and when they are activated during language production.
868 The model, which is based on Levelt's (1989) speech production model, takes as a starting point
869 the observation that language specific properties can interact with production mechanisms to lead
870 to differences with regard to information flow during sentence production (Vigliocco,
871 Butterworth, & Garrett, 1996)—an observation that has received independent support from prior
872 cross-linguistic research (e.g., Costa, Sebastián-Gallés, Miozzo, & Caramazza, 1999; Miozzo &
873 Caramazza, 1999; Schiller & Caramazza, 2003). Lexical access and grammatical encoding
874 during production are located in the formulation component (Levelt, 1989). This component
875 takes a speaker's non-linguistic conceptual message and transforms it into linguistic structure.
876 Words are accessed and ordered, and their sounds are retrieved and organized for articulation.

877 The formulation component is distinguished from a prior component responsible for message
878 formation (the conceptualizer) and from a subsequent one that executes articulatory movements
879 (Dell, Chang, & Griffin, 1999). The formulation component is commonly thought of as
880 involving two stages, a functional stage of processing and a positional stage. During functional
881 processing, speakers lexicalize concepts and generate functional structure (e.g., syntactic
882 information is specified and syntactic roles are assigned). During positional processing, the
883 retrieved lexical items are inflected and assembled into their appropriate position in the sentence
884 (see Jaeger & Norcliffe, 2009). The output of these two stages is then passed onto the phonetic
885 encoding and the articulatory processing (Bock & Levelt, 1994).

886 Returning now to the Spanish auxiliary system, according to Myers-Scotton and Jake
887 (2001), not all closed-class items are equal. Early system morphemes are free to participate in
888 code-switching, but late system morphemes, which are void of meaning and fulfill purely
889 syntactic functions, are structurally assigned and, hence, do not easily participate in code-
890 switching. The classification of *estar* as an early system morpheme and *haber* as a late system
891 morpheme is based on their respective within-language behavior. Although both are poly-
892 morphemic and convey tense and aspect, *haber* has lost its original meaning of ‘to have,’ or ‘to
893 possess’ (Coromines & Pascual, 1980). Modern day Spanish expresses possession using *tener*
894 (e.g., *él tiene una mascota* ‘he has a pet’). New verbs have also replaced periphrastic uses of
895 *haber*; hence, *haber alegría* ‘to have happiness’ is expressed in contemporary Spanish with
896 *alegrarse*; *haber miedo* ‘to have fright’ has become *asustarse*, and *haber nombre* ‘to have a
897 name’ is *llamarse* (García Gallarín, 2002, p. 20). In Spanish, *haber* as a lexical verb is only

898 employed as an existential (*hay cinco libros* ‘there are five books’), and in archaic (and non-
899 productive) phrases to express obligation (e.g., has *de verla* ‘you have to see her’). The argument
900 is that *haber* is simply a “placeholder” for grammatical features to be expressed orthographically
901 and phonologically during the positional stage in production. These properties of *haber*
902 considerably limit the possibility of a code-switch to be produced. In contrast to *haber*, *estar* is
903 more autonomous in its syntactic behavior. First, aside from being followed by the present
904 participle (*estoy trabajando* ‘I am working’), *estar* can be followed by other expressions, such as
905 adverbial and adjectival phrases (e.g., *estoy en el parque* ‘I am at the park,’ and *estoy molesto* ‘I
906 am angry’). In addition, intervening material is permissible between *estar* and a present
907 participle (e.g., *ella está siempre fastidiándonos* ‘she is always bothering us’). *Estar* and the
908 present participle can also switch syntactic positions, something not permissible with *haber* (e.g.,
909 *caminando estoy* ‘walking (I) am’). This indicates that *estar* is semantically more autonomous,
910 allowing for a code-switch to occur effortlessly in this context. If this analysis is correct, *estar* is
911 salient at the level of the mental lexicon, and switches involving the *estar*+participle
912 constructions should have no particular restrictions on their production, i.e., no restrictions
913 against code-switching, as is the case in other well-attested syntactic positions, such as switches
914 between a subject noun phrase and its corresponding verb phrase. *Haber*, on the other hand, has
915 purely grammatical functions and is salient only when late selected morphemes are structurally-
916 assigned; because of this, the entire *haber* verb phrase does not easily participate in code-
917 switching.

Admittedly, the production explanation provided here remains necessarily tentative because our understanding of the production forces that promote code-switching is in a very early stage. One general, albeit counter-intuitive hypothesis, is that bilinguals engage in code-switching partly to improve production fluency. We know that bilinguals are actually not capable of “turning off” another language entirely, even when the intention is to speak one language only (Kroll & Bialystok, 2013; Kroll, Bobb, Wodniecka, 2006; Kroll 2008). Given the parallel activity of a bilingual’s two languages, it may be that bilinguals code-switch, in part, to mitigate utterance planning difficulties that come from the parallel activation of their two languages. The fact that not all bilinguals code-switch suggests the presence of social forces and community-based norms that also affect whether or not bilinguals engage in code-switching (Myers-Scotton, 1993; Torres Cacoullos & Travis, 2015). But when code-switching is part of the linguistic repertoire of bilingual communities, it may be a strategy used to mitigate utterance planning difficulties that come from having words and sentence structures activated in parallel in both languages. In this sense, costs associated with the production of code-switches should be the exception and not the norm. We hope that the study of the relationship between the comprehension and production of code-switched language presented here has the consequence of increasing interest from production researchers to investigate the production forces that promote code-switching.

Linking production patterns to comprehension difficulty

938 The results of the eye-tracking study are congenial with models that propose that the
939 relative frequency of constructions, as quantified within a corpus, modulates comprehension
940 costs. The Production-Distribution-Comprehension (PDC) model (Gennari & MacDonald, 2009;
941 MacDonald, 2013; MacDonald & Thornton, 2009) is one such model. According to the PDC
942 model, the properties and mechanisms of the production system influence the structural choices
943 that individuals make during production, promoting certain lexical or structural pairings over
944 others. These production pressures, over time and across many speakers and writers, create
945 distributional patterns in the language input that comprehenders perceive. The distributional
946 patterns become the probabilistic constraints that guide comprehension in a constraint-based
947 system. Comprehenders implicitly learn from these patterns and interpret new input as consistent
948 with previous experience. Therefore, factors beyond the structural properties of language, such
949 as prior experience with particular structures, are considered to play a crucial role in the
950 comprehension of those structures. In other words, frequent linguistic structures are more readily
951 activated than less common structures, and are, therefore, easier to process during
952 comprehension. A similar notion is taken up in the P-chain framework (Dell & Chang, 2014),
953 which discusses the relation between psycholinguistic concepts, such as processing, prediction,
954 and production. A central aspect of the framework for the purposes of this study is the proposal
955 that processing involves prediction regarding upcoming structures and that this prediction is
956 influenced by the production systems of other speakers, which create production-biased
957 distributions that train comprehenders' processing systems. This experience in predicting, in

958 turn, trains production, resulting in a system in which both production and comprehension are
959 linked to each other and affected by previous linguistic experience.

960 Both of these approaches can be invoked to explain the eye-tracking results reported here.
961 As the corpus study showed, switches at the auxiliary involving the progressive structure are as
962 frequent in the bilinguals' linguistic experience (be it others' production practices or their own)
963 as switches at the participle; switches involving the perfect structure, however, are frequent if
964 they occur at the auxiliary, but infrequent at the participle. The relative frequency of these
965 switches in production obviously plays a key role. What is striking about the findings is the
966 evidence that bilinguals have developed sensitivity to detailed distributional information about
967 these two types of code-switches and that *this* modulates the bilinguals' comprehension
968 difficulty.

969 In concluding, a word is in order about the importance of converging evidence. Over
970 forty years of sentence-processing research has given rise to multiple models about the
971 architecture of the sentence-processing mechanism. For the vast majority of this period, the
972 evidential base in favor of one model or another has come from studies involving monolingual
973 speakers. During this time, many creative experimental designs using powerful data collection
974 tools have generated data that have been used to adjudicate among competing models. As might
975 be expected, some results are firmly in the camp that proposes one particular model, but, of
976 course, there is an extensive body of work that also favors an opposing model. In the very end,
977 the model that will prevail is likely to be the one capable of accounting for the most findings.
978 The work we presented here illustrates how we can expand the study of basic language processes

by exploiting the presence of two languages in a single mind. Our findings broadly suggest that bilingual code-switchers learn and store frequency information about multi-word code-switches, which they later use during comprehension. By looking at bilingual data, then, we add evidence to the processing literature that broadly supports a usage-based position.

1217 **Tables**

1218

1219 Table 1. Distribution of code-switches by syntactic site (Spanish to English switches)

	Oral Corpus (Miami)				Written Corpus (Gibraltar)			
	Progressive		Perfect		Progressive		Perfect	
	Tokens	%	Tokens	%	Tokens	%	Tokens	%
Switch immediately preceding auxiliary	3	3.22%	0	--	1	0.94%	1	.667%
Switch at auxiliary	7	7.53%	3	10.71%	8	7.55%	14	9.33%
Switch at participle	7	7.53%	0	--	8	7.55%	1	.667%
Switch immediately following participle	13	13.98%	6	21.43%	9	8.49%	28	18.67%
Switch elsewhere	63	67.74%	19	67.86%	80	75.47%	106	70.67%
Total	93	100%	28	100%	106	100%	150	100%

1220

1221 Table 2. Sample items in grammatical competency tests

Sample item from the MELICET	Sample item from the DELE
<p>“What is that thing?”</p> <p>“That _____ a spider.”</p> <p>a) to call</p> <p>b) for calling</p> <p>c) be called</p> <p>d) is called</p>	<p>En la compañía se está decidiendo estos días si _____ nuevos horarios para los trabajadores.</p> <p>a) haya</p> <p>b) habrá</p> <p>‘These days the Company is deciding whether _____ new schedules for the workers.</p> <p>a) there were</p> <p>b) there will be’</p>

1222

1223 Table 3. Participant characteristics

Characteristics	Early exposure participants (n = 42)	Late exposure participants (n = 27)
Age	21 (18-33)	22 (18-32)
Self-ratings for English proficiency (/10)	9.0 (5.75-10)	8.5 (5.75-10)
Self-ratings for Spanish proficiency (/10)	8.3 (5.75-10)	9.4 (7.5-10)
BNT score for English (/30)	20 (9-27)	16 (8-23)
BNT score for Spanish (/30)	14 (7-24)	21 (17-26)
MELICET score (/50)	40 (30-50)	41 (30-47)
DELE score (/50)	35 (20-45)	43 (33-48)

1224

1225 * Means are displayed with ranges in parentheses.

1226 Table 4. Example of experimental item set

Condition	Sample sentence
(1) Progressive-Switch at auxiliary	<i>El chef piensa que los turistas are <u>enjoying</u> the food at his gourmet restaurant.</i>
(2) Progressive-Switch at participle	<i>El chef piensa que los turistas están <u>enjoying</u> the food at his gourmet restaurant.</i>
(3) Perfect-Switch at auxiliary	<i>El chef piensa que los turistas have <u>enjoyed</u> the food at his gourmet restaurant.</i>
(4) Perfect-Switch at participle	<i>El chef piensa que los turistas han <u>enjoyed</u> the food at his gourmet restaurant.</i>

1228 Table 5. Results of the linear mixed-effects models for the sentence initial region (Region 1)

Measure	Variable	<i>b</i>	SE	<i>t</i>
First-pass	Intercept	1097.18	62.35	17.6
	Switch Position	28.12	42.2	0.62
	Auxiliary Type	52.51	55.94	0.94
	Group	-189.92	91.66	-2.07
	Switch Position * Auxiliary	-21.81	62.08	-0.35
	Switch Position * Group	-65.58	72.56	-0.9
	Auxiliary * Group	-136.1	71.23	-1.91
	Switch Position * Auxiliary * Group	134.09	99.43	1.35
Total Time	Intercept	2436.9	142.22	17.13
	Switch Position	-4.35	118.5	-0.04
	Auxiliary Type	65.02	138.19	0.47
	Group	-658.39	215.71	-3.05
	Switch Position * Auxiliary	-114.12	159.9	-0.71
	Switch Position * Group	-5.96	179.5	-0.03
	Auxiliary * Group	-37.43	197.79	-0.19
	Switch Position * Auxiliary * Group	192.02	240.61	0.8

1229 * Results for the linear mixed-effects models on first-pass reading time and total time. All
 1230 predictor variables were contrast coded (-0.5 = switch at auxiliary; progressive auxiliary; late
 1231 exposure group). Significant *t*-values are bolded.

1232 Table 6. Results of the linear mixed-effects models for the embedded subject region (Region 2)

Measure	Variable	<i>b</i>	SE	<i>t</i>
First-pass	Intercept	638.44	39.56	16.14
	Switch Position	15.28	33.76	0.45
	Auxiliary Type	-0.77	40.91	-0.02
	Group	-133.67	54.06	-2.47
	Switch Position * Auxiliary	-3.63	45.64	-0.08
	Switch Position * Group	-16.63	50.81	-0.33
	Auxiliary * Group	53.67	46.52	1.15
	Switch Position * Auxiliary * Group	-25.08	68.2	-0.37
Total Time	Intercept	1221.11	75.51	16.17
	Switch Position	-34.4	64	-0.54
	Auxiliary Type	56.02	80.7	0.69
	Group	-281.69	106.53	-2.64
	Switch Position * Auxiliary	-30.85	83.11	-0.37
	Switch Position * Group	17.73	96.34	0.18
	Auxiliary * Group	39.16	101.62	0.39
	Switch Position * Auxiliary * Group	38.13	123.5	0.31

1233 * Results for the linear mixed-effects models on first-pass reading time and total time. All
1234 predictor variables were contrast coded (-0.5 = switch at auxiliary; progressive auxiliary; late
1235 exposure group). Significant *t*-values are bolded.

1236 Table 7. Mean reading times and standard error on the critical region (participle, Region 3)

Measure	Switch Position	Late Exposure	Early Exposure
Progressive structure, e.g., <i>los turistas</i> are enjoying, <i>los turistas están</i> enjoying			
First-pass	At Auxiliary	368 (16.75)	350 (14.78)
	At Participle	409 (18.83)	388 (14.49)
Total Time	At Auxiliary	674 (29.78)	683 (34.97)
	At Participle	732 (40.31)	750 (29.09)
Perfect structure, e.g., <i>los turistas</i> have enjoyed, <i>los turistas han</i> enjoyed			
First-pass	At Auxiliary	355 (16.59)	311 (11.95)
	At Participle	440 (24.60)	438 (19.10)
Total Time	At Auxiliary	679 (36.05)	636 (26.71)
	At Participle	952 (46.12)	947 (39.32)

1237

1238 * Mean reading times in milliseconds for first-pass reading time and total time split by bilingual

1239 group with standard error presented in parentheses. Progressive conditions appear in the upper

1240 panel and Perfect conditions are presented in the lower panel.

1241 Table 8. Results of the linear mixed-effects models for the critical region (participle, Region 3)

Measure	Variable	<i>b</i>	SE	<i>t</i>
First-pass*	Intercept	348.75	24.83	14.05
	Switch Position	40.72	24.35	1.67
	Auxiliary Type	-39.1	24.74	-1.58
	Group	24.46	36.77	0.67
	Switch Position * Auxiliary	85.18	36.93	2.31
	Switch Position * Group	1.52	38.94	0.04
	Auxiliary * Group	18.78	33.71	0.56
	Switch Position * Auxiliary * Group	-35.8	58.91	-0.61
Total Time	Intercept	681.28	51.02	13.35
	Switch Position	72.37	40.39	1.79
	Auxiliary Type	-41.1	52.41	-0.78
	Group	11.33	72.09	0.16
	Switch Position * Auxiliary	241.17	64.55	3.74
	Switch Position * Group	-15.89	64.68	-0.25
	Auxiliary * Group	27.84	64.69	0.43
	Switch Position * Auxiliary * Group	-17.5	102.98	-0.17

1242 * Results for the linear mixed-effects models on first-pass reading time and total time. All
 1243 predictor variables were contrast coded (-0.5 = switch at auxiliary; progressive auxiliary; late
 1244 exposure group). Significant *t*-values are bolded. The model that converged with first-pass
 1245 reading time included random intercepts for Items.

1246 Table 9. Mean reading times and standard error on the first word post-participle region (Region
1247 4)

Measure	Switch Position	Late Exposure	Early Exposure
Progressive structure, e.g., <i>los turistas</i> are enjoying, <i>los turistas están</i> enjoying			
First-pass	At Auxiliary	107 (9.97)	129 (10.02)
	At Participle	117 (13.23)	131 (9.35)
Total Time	At Auxiliary	207 (16.02)	239 (15.5)
	At Participle	248 (20.71)	250 (17.28)
Perfect structure, e.g., <i>los turistas</i> have enjoyed, <i>los turistas han</i> enjoyed			
First-pass	At Auxiliary	108 (9.89)	123 (8.68)
	At Participle	158 (15.74)	162 (11.39)
Total Time	At Auxiliary	263 (27.65)	243 (14.77)
	At Participle	347 (29.66)	332 (18.43)

1248

1249 * Mean reading times in milliseconds for first-pass reading time and total time split by bilingual
1250 group with standard error presented in parentheses. Progressive conditions appear in the upper
1251 panel and Perfect conditions are presented in the lower panel.

1252

1253 Table 10. Results of the linear mixed-effects models for the first word post-participle region
 1254 (Region 4)

Measure	Variable	<i>b</i>	SE	<i>t</i>
First-pass	Intercept	130.46	13.99	9.33
	Switch Position	3.74	13.18	0.28
	Auxiliary Type	-6.47	16.94	-0.38
	Group	-20.17	18.63	-1.08
	Switch Position * Auxiliary	32.1	18.59	1.73
	Switch Position * Group	5.16	20.89	0.25
	Auxiliary * Group	0.91	20.73	0.04

	Switch Position * Auxiliary * Group	-23.38	66.41	-0.35

1260 * Results for the linear mixed-effects models on first-pass reading time and total time. All
 1261 predictor variables were contrast coded (-0.5 = switch at auxiliary; progressive auxiliary; late
 1262 exposure group). Significant *t*-values are bolded.

1263 **Figures**

1264

1265 Figure 1. Sample questions in LHQ

Did you begin to speak both English and Spanish before age 5?

Yes

No

In general, which language do you prefer to use?

English

Spanish

Both

It depends on whom I talk to

Code-switching means using both Spanish and English in the same sentence when you are talking to someone else. Do you ever code-switch?

Yes

No

Why do you think you code-switch?

1266

Color figure for Online version:

Figure 2. Mean first-pass reading time on the critical region (participle, Region 3)

* Mean reading times in milliseconds are presented for first-pass reading time on the participle for code-switches involving the progressive (*are/están*) and perfect (*have/han*) structures collapsed for bilingual group. For each auxiliary type, switches at the auxiliary (*los turistas are enjoying / have enjoyed*) are presented on the left. Error bars represent standard error of the mean.

Black-and-white figure for Print version:

Figure 2. Mean first-pass reading time on the critical region (participle, Region 3)

* Mean reading times in milliseconds are presented for first-pass reading time on the participle for code-switches involving the progressive (*are/están*) and perfect (*have/han*) structures collapsed for bilingual group. For each auxiliary type, switches at the auxiliary (*los turistas are enjoying / have enjoyed*) are presented on the left. Error bars represent standard error of the mean.

Color figure for Online version:

Figure 3. Mean total time on the critical region (participle, Region 3)

* Mean reading times in milliseconds are presented for total time on the participle for code-switches involving the progressive (*are/están*) and perfect (*have/han*) structures collapsed for bilingual group. For each auxiliary type, switches at the auxiliary (*los turistas are enjoying / have enjoyed*) are presented on the left. Error bars represent standard error of the mean.

Black-and-white figure for Print version:
