ABSTRACT

A series of artificial peptides bearing cationic functional groups with different side chain lengths were designed, and their ability to increase the thermal stability of nucleic acid duplexes was investigated. The peptides with amino groups selectively increased the stability of RNA/RNA duplexes, and a relationship between the side chain length and the melting temperature (T_m) of the peptide–RNA complexes was observed. On the other hand, while peptides with guanidino groups exhibited a similar tendency with respect to the peptide structure and thermal stability of RNA/RNA duplexes, those with longer side chain lengths, such as L-2-amino-4-guanidinobutyric acid (Agb) or L-arginine (Arg) oligomers, stabilized both RNA/RNA and DNA/DNA duplexes, and those with shorter side chain lengths exhibited a higher ability to selectively stabilize RNA/RNA duplexes. In addition, peptides were designed with different levels of flexibility by introducing glycine (Gly) residues into the L-2-amino-3-guanidinopropionic acid (Agp) oligomers. It was found that insertion of Gly did not affect the thermal stability of the peptide–RNA complexes, but an alternate arrangement of Gly and Agp apparently decreased the thermal stability. Therefore, in the Agp oligomer, consecutive Agp sequences of are essential for increasing the stability of RNA/RNA duplexes.

1. Introduction

In recent years, increased attention has been paid to the development of nucleic acid drugs. For example, antisense oligonucleotides and RNA interference drugs (RNAi drugs) are well known molecular tools for the regulation of gene expression, in which their mechanisms of action are based on sequence specific interactions¹. The RNAi drugs act on the target mRNA in a sequence selective manner. Thus, RNAi drugs are attractive because of their high selectivity for the target and their shorter drug development time. Therefore, siRNAs have been widely studied for therapeutic applications; however, such RNA molecules are not sufficiently effective because of their low-membrane permeability and instability in cells. To stabilize oligonucleotides against metabolic degradation, a number of chemical modifications have been proposed², and RNAi drugs generally consist of double stranded RNAs (dsRNAs) with chemical modifications. A proper modification of an RNA molecule increases its stability in cells and improves its pharmacokinetic properties³. Another strategy for stabilizing siRNA is the use of molecules that can non-covalently bind to RNA to protect it from attack by nucleases. For example, a fusion protein of the peptide transduction domain-dsRNA binding domain was shown to effectively transport RNAi drugs into primary cells⁴. In this case, the increased thermal stability of

the dsRNAs also increased their stability in cells⁵. We are thus attempting to develop RNA/RNA duplex-binding molecules that are useful as drug delivery systems (DDSs) for siRNAs.

A wide variety of RNA-binding molecules have been reported, such as aminoglycosides⁶ and RNA-binding proteins⁷. In particular, chemically modified peptides bearing different methylene lengths in the arginine or lysine residues possess diverse affinities to RNAs⁸. In our previous study, α -(1 $\rightarrow$ 4)-linked-2,6-diamino-2,6-dideoxy-D-glucopyranose oligomers were synthesized, and their highly RNA-selective binding ability was demonstrated⁹. These results suggested that the geometry of the cationic groups, particularly the distance between the cationic groups, affects the affinity and selectivity of the oligomers for nucleic acid duplexes. Therefore, in this study, we designed a series of cationic oligopeptides to reveal the relationship between the geometry of the cationic groups and the affinity of the peptides for nucleic acids. In contrast to oligosaccharide derivatives, peptides can easily be synthesized, which is advantageous for obtaining a systematic series of molecules. They can also be readily connected with other functional groups such as transporter molecules¹⁰. Therefore, RNA duplex-binding peptides are useful tools for the development of drug delivery systems (DDSs) for RNAi drugs. The L-arginine (Arg) oligomers designed from the HIV Tat peptide are well known for their high-membrane permeability¹¹ and the Arg 15mer has been used as an

RNAi transporter by forming a complex with RNA¹². However, the activity varies with the side chain length¹³, and thus a more detailed study of the relationship between the structure and activity is important for the development of effective carriers for RNAi drugs. Thus, to investigate the structural effects on binding ability, we designed and synthesized a number of cationic oligopeptides bearing different side chain lengths to control the distance between the cationic functional groups and peptides with different flexibility by incorporating glycine (Gly).

2. Results and Discussion

2.1. Design of the peptides

A series of cationic oligopeptides was designed (Fig. 1). All peptides contained a unit of *N*-acetyl-*L*-tyrosine with two glycine residues at the N-terminus for UV detection and quantification. In this study, the 12mer of nucleic acid duplexes was used as a model to estimate the interaction with peptides bearing four or eight cationic groups because four pairs of phosphate groups are aligned on the inward portion of the major groove of the 12mer of A-type nucleic acid duplexes. First, to compare the effects of the distance between cationic groups, peptides with different side chain lengths were designed. Peptides were synthesized with amino groups (*L*-2,3-diaminopropionic acid (Dap), *L*-2,4-diaminobutyric acid (Dab), *L*-ornithine (Orn), and *L*-lysine (Lys)) and guanidino groups (*L*-2-amino-3-guanidinopropionic acid (Agp), *L*-2-amino-4-guanidinobutyric acid (Agb), and *L*-arginine (Arg)). In some molecules, several glycine units were also inserted into an Agp octamer to increase the flexibility of the peptides. Peptides with alternate arrangements were also designed to change the position and combination of the functional groups. These peptides were based on the Agp oligomer and other amino acids such as glycine (Gly), *L*-serine (Ser), and *L*-asparagine (Asn). Glycine was chosen because of its high flexibility. Ser and Asn were chosen because they are well known in RNA-binding proteins to form hydrogen bonds with the phosphate groups of RNA¹⁴.

Peptides with amino groups	Peptides with flexible main chains	
Dap ₈ : Ac-YGG-Dap ₈ -NH ₂ 1	Agp ₈ G1 : Ac-YGG-Agp ₈ -G-Agp ₂ -NH ₂	8

Figure 1. Structures and sequences of cationic peptides.

On the basis of molecular mechanics calculations with a GB/SA water solvation model¹⁵, a cationic oligopeptide 8mer consisting of Dab can bind to the major groove of an A-type RNA/RNA duplex 12mer, in which all the protonated amino groups of the peptide form the hydrogen bonds to the phosphate anions of the duplex (Fig. 2). Therefore, the electrostatic interaction and hydrogen bonding would be important for the binding of cationic oligopeptides to RNA/RNA duplexes.

Figure 2. Molecular model of 2,4-L-diaminobutylic acid (Dab) 8mer binding to A-type RNA-RNA duplex (12mer).

2.2. Melting temperature (T_m) analysis

The T_m values of the RNA duplexes were measured both in the absence and presence of an equal amount of peptides. All measurements were performed under-physiological conditions with 10 mM phosphate buffer containing 100 mM NaCl at pH 7.0. Figure 2 shows the melting temperature enhancements and Table 1 lists the T_m values for the self complementary RNA 12mer r(CGCGAAUUCGCG)₂ in the absence and presence of an equal amount of peptides with amino groups. In this study, the peptides were added into the solution of nucleic acid duplexes after annealing to avoid the aggregation of the peptides at high temperature. The T_m values were affected by the side chain length, with Dab₈ (2) showing the highest T_m value. Comparing the Dab₈ (2), Orn₈ (3), and Lys₈ (4), the T_m value increased as the side chain length decreased. These results suggest that the distance between the amino groups in Dab₈ (2) fits to the distance of the opposing phosphate groups in the RNA duplexes. This tendency has been previously reported for cationic oligopeptides with α -amino acids⁶. On the other hand, Dap₈ (1) did not stabilize the RNA/RNA duplexes. This differing behavior may result because the distance of the amino groups in Dap₈ is too short to interact with the phosphate groups in the RNA/RNA duplexes. In fact, none of the peptides with amino groups increased the thermal stability of the DNA/DNA duplex d(CGCGAATTCGCG)₂ (Fig. 3). The distance between the phosphate groups in the major groove of a DNA/DNA duplex is twice that in an RNA/RNA duplex. Therefore, none of the peptides were able to interact with the DNA/DNA duplexes. In the minor groove of a DNA/DNA duplex, the interstrand phosphate groups are much closer than those in the major groove. However, the phosphate groups facing outwaed of the minor groove are unfavorable to form hydrogen bonds with the protonated amino groups of cationic peptides.

Figure 3. Melting temperature enhancements for the RNA/RNA and DNA/DNA duplexes at pH 7.0 in the presence of peptides **1-4**. Differences in the thermal melting points (ΔT_m) are given for the nucleic acid duplexes in the presence of equimolar amounts of peptide relative to the duplex alone. The dark gray columns represent ΔT_m for RNA/RNA duplex, and light gray columns represent ΔT_m values for DNA/DNA duplex.

Table 1. Thermal melting points (T_m in $^{\circ}\text{C}$) for oligonucleotide duplex (in the absence and presence of peptides with amino groups ^a). ^b

^bBuffer (10 mM phosphate buffer for pH 7.0), NaCl (100 mM), together with each oligonucleotide strand (4 μM). T_m values are reported at the means of duplicate measurements.

The peptides with guanidino groups (**5**, **6**, **7**) exhibited the same tendency as the peptides with the amino groups (Fig. 4, Table 2) for the RNA/RNA duplexes. Peptides with shorter side chain lengths had higher T_m values. This result indicates that the position of guanidino groups in Agp₈ (**5**) also fits well with the RNA duplex structure. While the distance between the functional groups is similar in the peptides with amino and guanidino groups, the peptides with the guanidino groups exhibited higher T_m values. These different T_m values can be attributed to the different features of the functional groups. The guanidino group is known to have a stronger interaction with phosphate groups than amino groups, and thus the peptides with guanidino groups showed a stronger interaction with the nucleic acid duplexes. However, in the case of the DNA/DNA duplex, the tendency changed because of the differences in the guanidino and amino functional groups. For the peptides with guanidine groups, those with longer side chain lengths had higher T_m values. This result may also be due to the fact that the guanidino groups strongly interact with the phosphate groups.

The different side chain lengths of the peptides resulted in different thermal stabilities of the nucleic acid duplexes. The duplex stability may also be affected by the flexibility of the peptides. Thus, to investigate the effect of incorporation of flexible residues into the peptide backbone, glycine was inserted into Agp₈ (**5**) to increase the flexibility of the main chain (**8**, **9**, **10**). Interestingly, it was found that an increase in the flexibility of the main chain did not affect the thermal stability of the peptide-RNA complexes (Fig. 5, Table 3). These results suggest that the stabilization of the RNA duplex with Agp₈ (**5**) is mainly

attributed to enthalpic factors. In addition, insertion of L-alanine (Ala) or L-proline (Pro) into Agp₈ (**5**) also did not affect the thermal stability of the RNA duplexes (**11**, **12**). If the peptides invade the major groove, the redundant amino acid residues will give rise to steric hindrance and decrease the thermal stability. Therefore, these results suggest that the peptides interact with the surface of the nucleic acids.

Figure 4. Melting temperature enhancements for the RNA/RNA and DNA/DNA duplexes at pH 7.0 in the presence of peptides **5-7**. Differences in the thermal melting points (ΔT_m) are given for the nucleic acid duplexes in the presence of an equal amount of peptide relative to the duplex alone. The dark gray columns represent ΔT_m for RNA/RNA duplex, and light gray columns represent ΔT_m values for DNA/DNA duplex.

^bBuffer (10 mM phosphate buffer for pH 7.0), NaCl (100 mM), together with each oligonucleotide strand (4 μ M). T_m values are reported at the means of duplicate measurements.

Peptides with alternate arrangements also did not stabilize the RNA duplexes (Fig. 6, Table 4). Peptides consisting of Agp and Gly in an alternate arrangement, AgpG (**13**) did not have any effects on the RNA/RNA duplex. On the other hand, Agp₄ showed an appreciable stabilization effect for the RNA/RNA duplex. Therefore, a consecutive Agp sequence is effective for RNA/RNA duplex stabilization. Furthermore, Agp₈G3 (**10**), in which four Agp₂ units are connected, has the same affinity as Agp₈; thus, the Agp₂ structural unit is effective for the interaction with RNA/RNA duplexes. In Agp oligomers with a consecutive sequence, the guanidino groups are located on both sides of the peptide backbone, and this alignment is identical to that required for interaction between the guanidino groups and the phosphates in the major groove of RNA duplexes. However, peptides with a combination of guanidino and hydroxy or amide groups (AgpS (**14**) and AgpN (**15**), respectively) had no effects on the thermal stability of RNA duplexes. These results also suggest that a consecutive arrangement of cationic amino acids is essential for effective interaction with the phosphates of RNA duplexes.

Figure 6. Melting temperature enhancements for the RNA/RNA duplexes at pH 7.0 in the presence of peptides **13–15**. Differences in the thermal melting points (ΔT_m) are given for the nucleic acid duplexes in the presence of equimolar amounts of peptide relative to the duplex alone.

^bBuffer (10 mM phosphate buffer for pH 7.0), NaCl (100 mM), together with each oligonucleotide strand (4 μ M). T_m values are reported at the means of duplicate measurements.

The effect of chirality was also examined. The Agp oligomers consisting of all-L- and all-D-amino acids had similar T_m values, but the peptides having D/L-alternate arrangements slightly had lower thermal stability. A decrease in the thermal stability induced by a heterochiral backbone was also reported for chiral PNA¹⁶.

2.3. CD spectroscopy

The structures of the peptides and the RNA-peptide complexes in solution were analyzed using circular dichroism (CD) spectroscopy. On the basis of molecular mechanics calculations¹⁵, the amino groups and guanidino groups of the peptides, particularly in Dap₈ (**2**) and Agp₈ (**5**), can form intramolecular hydrogen bonds with the amido groups in the main chain. However, in the absence of nucleic acid duplexes, the spectra of all the peptides indicated the presence of random coils¹⁷. Therefore, the effect of the secondary structures of the peptides was negligible in these cases. The structures of the RNA-peptide complexes were also analyzed. Because the peptides showed a variety of T_m values depending on the side chain length and the nature of the cationic functional groups, there existed not only electrostatic interactions and hydrogen bonding, but also structural factors. However, for both the RNA and DNA duplexes, no appreciable structural changes in the nucleic acids were observed following the addition of the peptides (Fig. 7, 8). The CD spectra of the RNA and DNA duplexes in the presence and absence of peptides were typical for A-type and B-type helices, respectively.

Figure 7. CD spectra of the RNA/RNA duplexes in the presence and absence of an equal amount of peptides **1–7** (at 20 °C, pH 7.0, 4 μ M each of peptide and duplex).

Figure 8. CD spectra of the DNA/DNA duplexes in the presence and absence of an equal amount of peptides 1-7 (at 20 °C, pH 7.0, 4 μ M each of peptide and duplex).

2.4. ITC measurement

Thermodynamic analysis of the peptide-nucleic acid interactions was carried out using isothermal titration calorimetry (ITC) measurements. The duplex concentration was 2.5 times higher than that used for the UV melting analyses because the amount of heat generated during the binding between the nucleic acid duplexes and the oligocationic peptides was expected to be insufficient for calculation of the thermodynamic parameters at the lower concentration. Fig. 9, S8¹⁷, and S9¹⁷ show the preliminary results for the ITC titration of the peptides with the self complementary RNA/RNA duplex r(CGCGAAUUCGCG)₂ and DNA/DNA duplex d(CGCGAATTCGCG)₂. In addition to electrostatic interactions and hydrogen bonding between the peptides and nucleic acids, dehydration and dissociation of the phosphates in the buffer solution were apparently observed. Thus, the interactions were too complex for calculation of the thermodynamical parameters. However, it was observed that both of the peptides selectively interacted with the RNA/RNA duplexes. In contrast, only Agb₈ (5) interacted with both the RNA/RNA and DNA/DNA duplexes. This result may be due to the fact that, in Agb₈, the side chain is long and sufficiently flexible to interact with the phosphate groups of both the RNA/RNA and DNA/DNA duplexes. In comparison with the amino-substituted Dap₈, the guanidine-substituted Dab₈ (5) had larger endothermic interactions.

Figure 9. ITC profiles at 25 °C for titration of Dab₈ (2) into a solution of RNA/RNA duplex (left) and DNA/DNA duplex (right); Each curve is the result of a 2.5 μ l injection of 150 μ M peptide. The duplex concentration was 10 μ M in a 10 mM phosphate buffer with 100 mM NaCl at pH 7.0; Corrected injection heat in the cases of RNA/RNA were plotted.

Inhibition assays were carried out to clarify the peptide-binding sites in the RNA duplexes. The peptides were titrated into a solution of the RNA duplexes in the presence of neomycin, which is known to bind to the major groove of RNA duplexes¹⁸. The inhibition of peptide-RNA binding by neomycin was different for the types of peptides (Fig. S10¹⁷). For Dab₈ (2), the exothermic interactions were selectively inhibited, while the endothermic interactions were still observed. On the other hand, for Agp₈ (5), both of the interactions were inhibited. These results suggest that the exothermic interactions are attributed to the binding of the peptides to the major groove of RNA/RNA duplexes and the endothermic interactions are related to the interactions with other sites.

3. Material and methods

3.1. Peptide synthesis

Peptides were synthesized via a conventional solid-phase method by using the 9-fluorenylmethoxycarbonyl (Fmoc) strategy¹⁹. The peptide chains were assembled on a Fmoc-NH-SAL-PEG resin by using Fmoc amino acid derivatives (5 equiv), *N,N*-diisopropylethylamine (DIPEA, 10 equiv), and 2-(1*H*-9-azabenzotriazole-1-yl)-1,1,3,3-tetramethyluronium hexafluorophosphate (HATU, 5 equiv) in dimethylformamide (DMF) for the coupling, and 25% piperidine/DMF for the removal of the Fmoc group. After coupling of the last amino acids, amino groups at the *N*-termini were protected with an acetyl (Ac) group using acetic anhydride (10 equiv). To cleave the peptide from the resin and remove the side chain protecting groups, the peptide resin was treated with trifluoroacetic acid (TFA)-triisopropylsilane-water, (95:2.5:2.5, v/v/v). Peptides in sat NaHCO_{3aq} (200 μ l) were added in one portion to a solution of the 1,3-di-Boc-2-(trifluoromethylsulfonyl)guanidine²⁰ (10 equiv per amino groups) in dioxane (200 μ l), and stirred overnight at rt, then concentrated in vacuo. To remove the protecting groups from the guanidino groups, the peptides were treated with TFA-triisopropylsilane-water (95:2.5:2.5, v/v/v). All peptides were purified with reverse-phase HPLC (0.05% TFA in water-acetonitrile). The peptides were successfully identified by matrix-assisted laser desorption ionization time-of-flight mass spectrometry (MALDI-TOF-MS). Compound 1, TOF-MS *m/z* calcd for [M+Na]⁺ 1048.07; Found 1047.60. Compound 2, TOF-MS *m/z* calcd for [M+H]⁺ 1138.31; Found 1137.22. Compound 3, TOF-MS *m/z* calcd for [M+Na]⁺ 1272.50; Found 1271.56. Compound 4, TOF-MS *m/z* calcd for [M+H]⁺ 1362.73; Found 1361.51. Compound 5, TOF-MS *m/z* calcd for [M+H]⁺ 1362.41; Found 1361.51. Compound 6, TOF-MS *m/z* calcd for [M+H]⁺ 1474.63; Found 1473.77. Compound 7, TOF-MS *m/z* calcd for [M+H]⁺ 1586.84; Found 1585.72. Compound 8, TOF-MS *m/z* calcd for [M+H]⁺ 1419.46; Found 1418.53. Compound 9, TOF-MS *m/z* calcd for [M+Na]⁺ 1476.52; Found 1476.00. Compound 10, TOF-MS *m/z* calcd for [M+H]⁺ 1533.57; Found 1533.07. Compound 11, TOF-MS *m/z* calcd for [M+H]⁺ 1504.57; Found 1504.21. Compound 12, TOF-MS *m/z* calcd for [M+H]⁺ 1556.64; Found 1555.68. Compound 13, TOF-MS *m/z* calcd for [M+Na]⁺ 1100.07; Found 1099.25. Compound 14, TOF-MS *m/z* calcd for [M+H]⁺ 1198.18; Found 1197.67. Compound 15, TOF-MS *m/z* calcd for [M+H]⁺ 1306.29; Found 1305.46.

3.2. Melting temperature (*T_m*) analysis

Absorbance versus temperature profile measurements were carried out in quartz cells with a 1 cm path length using an eight-sample cell changer. The variation in the UV absorbance with temperature was monitored at 260 nm. The temperature was scanned from 10 to 95 °C at a rate of 0.2 °C/min. The peptides were added after oligonucleotides were annealed. The samples

were prepared as follows. The oligonucleotides were dissolved in a phosphate buffer (10 mM) containing NaCl (0.1 M) at pH 7.0. The solutions of oligonucleotides (4 μ M) were first rapidly heated to 95 °C, left for 10 min, and then cooled to 10 °C at a rate of 1 °C/min. The equal amounts of peptides (final conc: 4 μ M) were then added to the solution. The samples were left to equilibrate at the starting temperature for 30 min, the dissociation of the duplex was observed by heating the solution to 95 °C at a rate of 0.2 °C/min, and data points were collected at every 0.1 °C.

3.3. CD spectroscopy

All CD spectra were recorded at 25 °C. The following instrument settings were used: resolution, 0.1 nm; sensitivity, 10 mdeg; response, 4 s; speed, 10 nm/min; accumulation, 6.

3.4. Conditions for ITC experiments

The peptides and nucleic acid duplexes were dissolved in a 10 mM phosphate buffer containing 100 mM NaCl at pH 7.0. The peptide solutions (150 μ M) were titrated into the nucleic acid duplex solutions (10 μ M) at 25 °C. Each titration of peptide solution consisted of a preliminary 0.5 μ l injection followed by 24 subsequent 1.5 μ l additions, which were performed over 3 s periods at 120 s intervals. In the inhibition assays, the peptide solutions were titrated into the nucleic acid solution in the presence of 100 μ M neomycin under the same conditions as described above

4. Conclusion

We have synthesized a series of cationic oligopeptides by systematically changing the position of the cationic groups. On the basis of UV-melting analysis, CD spectrometry and ITC measurements, these cationic oligopeptides showed different tendencies for the stabilization of nucleic acid duplexes. Peptides with amino groups stabilized only RNA duplexes, while peptides with guanidino groups stabilized both RNA and DNA duplexes. In particular, Dab₈ (**2**) and Agp₈ (**5**) showed the highest T_m values among the series of peptides with the same cationic groups but different side chain length. These results suggest that the distance between the cationic groups, such as in Dab₈ (**2**) and Agp₈ (**5**), are well fitted to the distance between the phosphate groups in the major groove of RNA duplexes. Furthermore, peptides with alternate arrangements and those containing flexible amino acids did not stabilize the RNA duplexes. These results indicate that at least two consecutive sequences of Agp are necessary for effective binding of cationic oligopeptides to RNA duplexes. Therefore, given their unique properties, Dab₈ (**2**) and Agp₈ (**5**) will be useful as stabilizers of dsRNA-based nucleic acid drugs or new materials for their DDS.

Acknowledgments

We thank Professor Kohei Tsumoto (University of Tokyo) and Dr. Satoru Nagatoishi (University of Tokyo) for the ITC measurements and helpful discussions. This work was finally supported by KAKENHI and CREST, the Japan Science and Technology Agency.
